## APPLICATION FOR UNITED STATES LETTERS PATENT

# SPECIFICATION

---

TO ALL WHOM IT MAY CONCERN:

Be it known that we, Kari Alitalo a citizen of Finland, residing at Nyyrikintie 4A, 02100 Espoo, Finland, and Vladimir Joukov a citizen of Russia, residing at Topeliuksenkatu 32G8, 00290 Helsinki, Finland, have invented a new and useful "RECEPTOR LIGAND VEGF-C", of which the following is a specification.

00 071573

- 1 -

### RECEPTOR LIGAND VEGF-C

This application is a continuation-in-part of United States Patent Application Serial Number 08/601,132, filed February 14, 1996, which is a continuation-in-part of United States Patent Application Serial Number 08/585,895, filed January \_\_, 1996, which is a continuation-in-part of United States Patent Application Serial Number 08/510,133, filed August 1, 1995. This application also is a continuation-in-part of United States Patent Application Serial Number 08/340,011, filed November 14, 1994.

### FIELD OF THE INVENTION

The present invention generally relates to the field of genetic engineering and more particularly to growth factors for endothelial cells and growth factor genes.

### BACKGROUND OF THE INVENTION

Developmental growth, the remodelling and regeneration of adult tissues, as well as solid tumor growth, can only occur when accompanied by blood vessel formation. Angioblasts and hematopoietic precursor cells differentiate from the mesoderm and form the blood islands of the yolk sac and the primary vascular system of the embryo. The development of blood vessels from these early (*in situ*) differentiating endothelial cells is termed vasculogenesis. Major embryonic blood vessels are believed to arise via vasculogenesis, whereas the formation of the rest of the vascular tree is thought to occur as a result of vascular sprouting from pre-existing vessels, a process called angiogenesis, Risau *et al.*, *Devel. Biol.*, 125:441-450 (1988).

Endothelial cells give rise to several types of functionally and morphologically distinct vessels. When organs differentiate and begin to perform their specific functions, the phenotypic heterogeneity of endothelial cells increases. Upon angiogenic stimulation, endothelial cells may re-enter the cell cycle, migrate, withdraw from the cell cycle and subsequently differentiate again to form new vessels that are functionally adapted to their tissue environment. Endothelial cells undergoing angiogenesis degrade the underlying basement membrane and migrate, forming capillary sprouts that project into the perivascular stroma. Ausprunk *et al.*, *Microvasc. Rev.*, 14:51-65 (1977). Angiogenesis during tissue development and regeneration depends

on the tightly controlled processes of endothelial cell proliferation, migration, differentiation, and survival. Dysfunction of the endothelial cell regulatory system is a key feature of many diseases. Most significantly, tumor growth and metastasis have been shown to be angiogenesis dependent. Folkman *et al.*, *J. Biol. Chem.*, 267:10931-10934 (1992).

Key signals regulating cell growth and differentiation are mediated by polypeptide growth factors and their transmembrane receptors, many of which are tyrosine kinases. Autophosphorylated peptides within the tyrosine kinase insert and carboxyl-terminal sequences of activated receptors are commonly recognized by kinase substrates involved in signal transduction for the readjustment of gene expression in responding cells. Several families of receptor tyrosine kinases have been characterized. Van der Geer *et al.*, *Ann. Rev. Cell Biol.*, 10:251-337 (1994). The major growth factors and receptors transducing angiogenic stimuli are schematically shown in Fig. 1.

Fibroblast growth factors are also known to be involved in the regulation of angiogenesis. They have been shown to be mitogenic and chemotactic for cultured endothelial cells. Fibroblast growth factors also stimulate the production of proteases, such as collagenases and plasminogen activators, and induce tube formation by endothelial cells. Saksela *et al.*, *Ann. Rev. Cell Biol.*, 4:93-126 (1988). There are two general classes of fibroblast growth factors, FGF-1 and FGF-2, both of which lack conventional signal peptides. Both types have an affinity for heparin and FGF-2 is bound to heparin sulfate proteoglycans in the subendothelial extracellular matrix from which it may be released after injury. Heparin potentiates the stimulation of endothelial cell proliferation by angiogenic FGFs, both by protecting against denaturation and degradation and dimerizing the FGFs. Cultured endothelial cells express the FGF-1 receptor but no significant levels of other high-affinity fibroblast growth factor receptors.

Among other ligands for receptor tyrosine kinases, the platelet derived growth factor, PDGF-BB, has been shown to be weakly angiogenic in the chick chorioallantoic membrane. Risau *et al.*, *Growth Factors*, 7:261-266 (1992). Transforming growth factor  $\alpha$  (TGF $\alpha$ ) is an angiogenic factor secreted by several tumor cell types and by macrophages. Hepatocyte growth factor (HGF), the ligand of the *c-met* proto-oncogene-encoded receptor, also is strongly angiogenic.

Recent evidence shows that there are endothelial cell specific growth factors and receptors that may be primarily responsible for the stimulation of endothelial cell growth, differentiation and certain differentiated functions. The best studied of these is vascular-endothelial growth factor (VEGF), a member of the PDGF family. Vascular endothelial growth factor is a dimeric glycoprotein of disulfide-linked 23 kD subunits. Other reported effects of VEGF include the mobilization of intracellular calcium, the induction of plasminogen activator and plasminogen activator inhibitor-1 synthesis, stimulation of hexose transport in endothelial cells, and promotion of monocyte migration *in vitro*. Four VEGF isoforms, encoded by distinct mRNA splice variants, appear to be equally capable of stimulating mitogenesis in endothelial cells. However, each isoform has a different affinity for cell surface proteoglycans, which behave as low affinity receptors for VEGF. The 121 and 165 amino acid isoforms of VEGF (VEGF<sub>121</sub> and VEGF<sub>165</sub>) are secreted in a soluble form, whereas the isoforms of 189 and 206 amino acid residues remain cell surface-associated and have a strong affinity for heparin. VEGF was originally purified from several sources on the basis of its mitogenic activity toward endothelial cells, and also by its ability to induce microvascular permeability, hence it is also called vascular permeability factor (VPF).

The pattern of VEGF expression suggests its involvement in the development and maintenance of the normal vascular system and in tumor angiogenesis. During murine development, the entire 7.5 day post-coital (p.c.) endoderm expresses VEGF and the ventricular neuroectoderm produces VEGF at the capillary ingrowth stage. See Breier *et al.*, *Development*, 114:521-523 (1992). On day two of quail development, the vascularized area of the yolk sac as well as the whole embryo show expression of VEGF. In addition, epithelial cells next to fenestrated endothelia in adult mice show persistent VEGF expression, suggesting a role in the maintenance of this specific endothelial phenotype and function.

Two high affinity receptors for VEGF have been characterized. These are VEGFR-1/Flt-1 (fms-like tyrosine kinase-1) and VEGFR-2/Kdr/Flk-1 (kinase insert domain containing receptor/fetal liver kinase-1). These receptors are classified in the PDGF-receptor family, but they have seven rather than five immunoglobulin-like loops in their extracellular domain and

they possess a longer kinase insert than normally observed in this family. The expression of VEGF receptors occurs mainly in vascular endothelial cells, although some may be present on monocytes and melanoma cells. Only endothelial cells have been reported to proliferate in response to VEGF, and  
5 endothelial cells from different sources show different responses. Thus, the signals mediated through VEGFR-1 and VEGFR-2 appear to be cell type specific. The VEGF-related placenta growth factor (PlGF) was recently shown to bind to VEGFR-1 with high affinity. PlGF was able to enhance the growth factor activity of VEGF, but it did not stimulate endothelial cells on its own.  
10 Naturally occurring VEGF/PlGF heterodimers were nearly as potent mitogens as VEGF homodimers for endothelial cells.

The Flt4 receptor tyrosine kinase (VEGFR-3) is closely related in structure to the products of the VEGFR-1 and VEGFR-2 genes. Despite this similarity, the mature form of Flt4 differs from the VEGF receptors in  
15 that it is proteolytically cleaved in the extracellular domain into two disulfide-linked polypeptides. Pajusola *et al.*, *Cancer Res.*, 52:5738-5743 (1992). The 4.5 and 5.8 kb Flt4 mRNAs encode polypeptides which differ in their C-termini due to the use of alternative 3' exons. The VEGFs do not show specific binding to Flt4 or induce its autophosphorylation.

20 Expression of Flt4 appears to be more restricted than expression of VEGFR-1 or VEGFR-2. The expression of Flt4 first becomes detectable by *in situ* hybridization in the angioblasts of head mesenchyme, the cardinal vein, and extraembryonically in the allantois of 8.5 day p.c. mouse embryos. In 12.5 day p.c. embryos the Flt4 signal is observed in developing venous and  
25 presumptive lymphatic endothelia, but arterial endothelia appear negative. During later stages of development, Flt4 mRNA becomes restricted to developing lymphatic vessels. Only the lymphatic endothelia and some high endothelial venules express Flt4 mRNA in adult human tissues and increased expression occurs in lymphatic sinuses in metastatic lymph nodes and in  
30 lymphangioma. These results support the theory of the venous origin of lymphatic vessels.

Five endothelial cell specific receptor tyrosine kinases, Flt-1 (VEGFR-1), KDR/Flk-1 (VEGFR-2), Flt4, Tie and Tek/Tie-2 have so far been described, which possess the intrinsic tyrosine kinase activity essential for  
35 signal transduction. Targeted mutations inactivating Flt-1, Flk-1, Tie and Tek

in mouse embryos have indicated their essential and specific roles in  
vasculogenesis and angiogenesis at the molecular level. VEGFR-1 and  
VEGFR-2 bind VEGF with high affinity ( $K_d$  16 pM and 760 pM, respectively)  
and VEGFR-1 also binds the related placenta growth factor (PlGF;  $K_d$  about  
5 200 pM), while the ligands for Tie, Tek, and Flt4 have not heretofore been  
reported.

#### SUMMARY OF THE INVENTION

The present invention provides a ligand for the Flt4 receptor  
tyrosine kinase. Thus, the invention provides a purified and isolated  
10 polypeptide which is capable of binding to the Flt4 receptor tyrosine kinase.  
Preferably, an Flt4 ligand of the invention is capable of stimulating tyrosine  
phosphorylation of Flt4 receptor tyrosine kinase in a host cell expressing the  
Flt4 receptor tyrosine kinase. Preferred ligands of the invention are  
mammalian polypeptides. Highly preferred ligands are human polypeptides.

15 In one embodiment, an FLT4 ligand has a molecular weight of  
approximately 23 kD as determined by SDS-PAGE under reducing conditions.  
For example, the invention includes a ligand composed of one or more  
polypeptides of approximately 23 kD is purifiable from conditioned media  
from a PC-3 prostatic adenocarcinoma cell line, the cell line having ATCC  
20 Acc. No. CRL 1435. Amino acid sequencing of this PC-3 cell derived ligand  
revealed that the ligand comprises an amino terminal amino acid sequence set  
forth in SEQ ID NO: 13. A conditioned medium comprising an Flt4 ligand is  
itself an aspect of the invention.

In a highly preferred embodiment, the ligand comprises a  
25 fragment of the amino acid sequence shown in SEQ ID NO: 33 which  
specifically binds to the human Flt4 receptor tyrosine kinase. Exemplary  
fragments include: a polypeptide comprising an amino acid sequence set forth  
in SEQ ID NO: 33 from about residue 112 to about residue 213; a polypeptide  
comprising an amino acid sequence from about residue 104 to about residue  
30 227 of SEQ ID NO: 33; and a polypeptide comprising an amino acid sequence  
from about residue 112 to about residue 227 of SEQ ID NO: 33. Other  
exemplary fragments include polypeptides comprising amino acid sequences of  
SEQ ID NO: 33 that span, approximately, the following residues: 31-213, 31-  
227, 32-227, 103-217, 103-225, 104-213, 113-213, 103-227, 113-227, 131-

211, 161-211, 103-225, 227-419, 228-419, 31-419, and 1-419, as described in greater detail below.

The present invention also provides one or more polypeptide precursors of an Flt4 ligand, wherein one such precursor (designated "prepro-VEGF-C") comprises the complete amino acid sequence (amino acid residues 1 to 419) shown in SEQ ID NO: 33. Thus, the invention includes a purified and isolated polypeptide having the amino acid sequence of residues 1 to 419 shown in SEQ ID NO: 33. A putative 102 amino acid leader (prepro) peptide has been identified in the amino acid sequence shown in SEQ ID NO: 33. Thus, in a related aspect, the invention includes a purified and isolated polypeptide having the amino acids sequence of residues 103-419 shown in SEQ ID NO: 33.

In one embodiment, an expressed Flt4 ligand precursor is proteolytically cleaved upon expression to produce an approximately 23 kD polypeptide which is the Flt4 ligand (herein designated VEGF-C). Thus, an Flt4 ligand is provided which is the cleavage product of the precursor peptide shown in SEQ ID NO: 33 and which has a molecular weight of approximately 23 kD under reducing conditions.

A putative VEGF-C precursor or splice variant, consisting of polypeptides with molecular weights of about 29 and 32 kD, also is considered an aspect of the invention.

In another embodiment, an expressed Flt4 ligand precursor is proteolytically cleaved upon expression to produce an approximately 21 kD VEGF-C polypeptide. Sequence analysis has indicated that an observed 21 kD form has an amino terminus approximately 9 amino acids downstream from the amino terminus of the 23 kD form, suggesting alternative cleavage sites exist.

From the foregoing, it will be apparent that an aspect of the invention includes a fragment of the purified and isolated polypeptide having the amino acid sequence of residues 1 to 419 shown in SEQ ID NO: 33, the fragment being capable of specifically binding to Flt4 receptor tyrosine kinase. Preferred embodiments include fragments having an apparent molecular weight of approximately 21/23 kD and 29/32 kD as assessed by SDS-PAGE under reducing conditions.

Evidence suggests that the amino acids essential for retaining

Flt4 ligand activity are contained within approximately amino acids 103/112-226/227 of SEQ ID NO: 33, and that a carboxy-terminal proteolytic cleavage to produce a mature, naturally-occurring Flt4 ligand occurs at the approximate position of amino acids 226-227 of SEQ ID NO: 33. Accordingly, a preferred  
5 Flt4 ligand comprises approximately amino acids 103-227 of SEQ ID NO: 33.

VEGF-C mutational analysis described herein indicates that a naturally occurring VEGF-C polypeptide spanning amino acids 103-227 of SEQ ID NO: 33, produced by a natural processing cleavage that defines the C-terminus, exists and is biologically active as an Flt4 ligand. A polypeptide  
10 fragment consisting of residues 104-213 of SEQ ID NO: 33 has been shown to retain VEGF-C biological activity. Additional mutational analyses indicate that a polypeptide spanning only amino acids 113-213 of SEQ ID NO: 33 retains Flt4 ligand activity. Accordingly, preferred polypeptides comprise sequences spanning, approximately, amino acid residues 103-227, 104-213, or  
15 113-213, of SEQ ID NO: 33.

Moreover, sequence comparisons of members of the VEGF family of polypeptides provide an indication that still smaller fragments will retain biological activity, and such smaller fragments are intended as aspects of the invention. In particular, eight highly conserved cysteine residues of the  
20 VEGF family of polypeptides define a region from residues 131 - 211 of SEQ ID NO: 33 (see Figures 10 & 31B); therefore, a polypeptide spanning from about residue 131 to about residue 211 is expected to retain VEGF-C biological activity. In fact, a polypeptide comprising approximately residues  
161-211, which retains an evolutionarily-conserved RCXXCC motif, is  
25 postulated to retain VEGF-C activity, and therefore is intended as an aspect of the invention. Some of the conserved cysteine residues in VEGF-C participate in interchain disulfide bonding to make homo- and heterodimers of the various naturally occurring VEGF-C polypeptides. Beyond the preceding considerations, evidence exists that VEGF-C polypeptides lacking interchain  
30 disulfide bonds retain VEGF-C biological activity. In particular, VEGF-C that has been reduced and alkylated (processes that prevent the formation of disulfide bonds by cysteine residues) retains biological activity. Consequently, the materials and methods of the invention include all VEGF-C fragments that retain at least one biological activity of VEGF-C, regardless of the presence or  
35 absence of interchain disulfide bonds. The invention also includes multimers

comprising such fragments linked to each other or to other polypeptides. Fragment linkage may be by way of covalent bonding (e.g., disulfide bonding) or non-covalent bonding of polypeptide chains (e.g., hydrogen bonding, bonding due to stable or induced dipole-dipole interactions, bonding due to hydrophobic or hydrophilic interactions, combinations of these bonding mechanisms, and the like).

In yet another related aspect, the invention includes variants and analogs of the aforementioned polypeptides, including VEGF-C, precursors of VEGF-C, and fragments of VEGF-C. The variants contemplated by the invention include purified and isolated polypeptides having amino acid sequences that differ from the amino acid sequences of VEGF-C, VEGF-C precursors and VEGF-C fragments by conservative substitutions, as recognized by those of skill in the art, or by additions or deletions of amino acid residues that are compatible with the retention of at least one biological activity of VEGF-C.

Analogous contemplated by the invention include polypeptides having modifications to one or more amino acid residues that differ from the modifications found in VEGF-C, VEGF-C precursors, or VEGF-C fragments, but are compatible with the retention of at least one biological activity of VEGF-C, VEGF-C precursors, or VEGF-C fragments. For example, analogs within the scope of the invention include glycosylation variants and conjugates (attachment of the aforementioned polypeptides to compounds such as labels, toxins, etc.)

The present invention also provides purified and isolated polynucleotides (i.e., nucleic acids) encoding novel polypeptides, for example a cDNA or corresponding genomic DNA encoding VEGF-C. VEGF-C is a ligand for the FLT4 receptor tyrosine kinase (VEGFR-3), a receptor tyrosine kinase related to VEGFR-1 and VEGFR-2 that does not bind VEGF. VEGFR-3 is expressed in venous and lymphatic endothelia of fetal tissues and predominantly in lymphatic endothelia of adult tissues. Kaipainen *et al.*, *Cancer Res.*, 54:6571-77 (1994); Kaipainen, *et al.*, *Proc. Natl. Acad. Sci. (USA)*, 92:3566-70 (1995). A preferred nucleic acid of the invention encodes VEGF-C, for example a DNA encoding amino acid residues 1 to 419 of SEQ ID NO: 33. Other preferred nucleic acids encode one of the aforementioned fragments of VEGF-C. The invention also comprehends analogs of these

polynucleotides, or derivatives of any one of these polynucleotides sufficiently duplicative of the corresponding naturally occurring polynucleotide such that the encoded polypeptide retains at least one biological property of the polypeptide encoded by the naturally occurring polynucleotide. DNA  
5 polynucleotides according to the invention include genomic DNAs, cDNAs, and oligonucleotides comprising the coding sequence for a fragment of VEGF-C, or an analog of a VEGF-C fragment that retains at least one of the biological activities of a VEGF-C fragment. Distinct polynucleotides encoding a polypeptide of the invention by virtue of the degeneracy of the genetic code  
10 are within the scope of the invention.

A preferred polynucleotide according to the invention comprises the human VEGF-C cDNA sequence set forth in SEQ ID NO: 32 from nucleotide 352 to 1611. Other polynucleotides according to the invention encode a VEGF-C polypeptide from, *e.g.*, mammals other than humans. Still  
15 other polynucleotides of the invention comprise a coding sequence for a VEGF-C fragment, and allelic variants of those DNAs encoding part or all of VEGF-C. Moreover, the invention comprehends polynucleotides that differ from native VEGF-C-encoding polynucleotides by the deletion, insertion or substitution of nucleotides and which encode polypeptides that retain part or all  
20 of at least one of the biological activities associated with native VEGF-C-encoding polynucleotides. Further, the invention contemplates polynucleotides having sequences that differ from polynucleotides encoding a VEGF-C fragment in a manner that results in conservative amino acid differences between the encoded polypeptides, as understood by those of skill in the art.

25 The invention further comprises polynucleotides that hybridize to the above-defined polynucleotides under standard stringent hybridization conditions, or which would hybridize but for the degeneracy of the genetic code. Exemplary stringent hybridization conditions are as follows: hybridization at 42°C in 50% formamide, 5X SSC, 20 mM Na•PO<sub>4</sub>, pH 6.8  
30 and washing in 0.2X SSC at 55°C. It is understood by those of skill in the art that variation in these conditions occurs based on the length and GC nucleotide content of the sequences to be hybridized. Formulas standard in the art are appropriate for determining exact hybridization conditions. See Sambrook *et al.*, *Molecular Cloning: A Laboratory Manual* (Second ed., Cold Spring Harbor Laboratory Press 1989) §§ 9.47-9.51. These polynucleotides, capable  
35

of hybridizing to polynucleotides encoding VEGF-C, VEGF-C fragments, or VEGF-C analogs, are useful as nucleic acid probes for identifying, purifying and isolating polynucleotides encoding other (non-human) mammalian forms of VEGF-C. Additionally, these polynucleotides are useful in screening methods  
5 of the invention, as described below.

Preferred nucleic acid probes of the invention comprise nucleic acid sequences of at least about 16 continuous nucleotides of SEQ ID NO: 32. More preferably, these nucleic acid probes would have at least about 20  
10 nucleotides found in a subsequence of SEQ ID NO: 32. In using these nucleic acids as probes, it is preferred that the nucleic acids specifically hybridize to a portion of the sequence set forth in SEQ ID NO: 32. Specific hybridization is herein defined as hybridization under standard stringent hybridization conditions. To identify and isolate other mammalian VEGF-C genes specifically, nucleic acid probes preferably are selected such that they fail to  
15 hybridize to genes related to VEGF-C (*e.g.*, fail to hybridize to human VEGF or to human VEGF-B genes).

Thus, the invention comprehends polynucleotides comprising at least about 16 nucleotides wherein the polynucleotides are capable of specifically hybridizing to a gene encoding VEGF-C, *e.g.*, a human gene.  
20 The specificity of hybridization ensures that a polynucleotide of the invention is able to hybridize to a nucleic acid encoding a VEGF-C under hybridization conditions that do not support hybridization of the polynucleotide to nucleic acids encoding, *e.g.*, VEGF or VEGF-B. In one embodiment, polynucleotides of at least about 16 nucleotides, and preferably at least about 20 nucleotides,  
25 are selected as continuous nucleotide sequences found in SEQ ID NO: 32 or the complement of the nucleotide sequence set forth in SEQ ID NO: 32.

Thus, aspects of the invention include purified and isolated nucleic acids encoding polypeptides and polypeptide fragments of the invention; vectors which comprise nucleic acids of the invention; and host cells  
30 transformed or transfected with nucleic acids or vectors of the invention. For example, in a preferred embodiment, the invention includes a purified and isolated nucleic acid (*e.g.*, a DNA or an RNA) encoding an Flt4 ligand precursor. Due to the degeneracy of the genetic code, numerous such coding sequences are possible, each having in common the coding of the amino acid  
35 sequence shown in SEQ ID NO: 33. As set forth above, the invention

includes polypeptides which comprise a portion of the amino acid sequence shown in SEQ ID NO: 33 and which bind the Flt4 receptor tyrosine kinase (herein designated VEGFR-3); the invention also is intended to include nucleic acids encoding these polypeptides. Ligand precursors according to the invention, when expressed in an appropriate host cell, produce, via cleavage, a peptide which binds specifically to the Flt4 receptor tyrosine kinase (VEGFR-3). The nucleotide sequence shown in SEQ ID NO: 32 contains a preferred nucleotide sequence encoding the Flt4 ligand (VEGF-C).

10 The present invention also provides a cell line which produces an Flt4 ligand. In a preferred embodiment, the ligand may be purified and isolated directly from the cell culture medium. Also provided are vectors comprising a DNA encoding the Flt4 ligand, and host cells comprising the vectors. Preferred vectors of the invention are expression vectors wherein nucleic acids of the invention are operatively connected to appropriate  
15 promoters and other control sequences, such that appropriate host cells transformed or transfected with the vectors are capable of expressing the Flt4 ligand. A preferred vector of the invention is plasmid pFLT4-L, having ATCC accession no. 97231. Such vectors and host cells are useful for recombinantly producing VEGF-C polypeptides.

20 The invention further includes a method of making polypeptides of the invention. In a preferred method, a nucleic acid or vector of the invention is expressed in a host cell, and a polypeptide of the invention is purified from the host cell or the host cell's growth medium.

In a related embodiment, the invention includes a method of  
25 making a polypeptide capable of specifically binding to Flt4 receptor tyrosine kinase, comprising the steps of: (a) transforming or transfecting a host cell with a nucleic acid of the invention; (b) cultivating the host cell to express the nucleic acid; and (c) purifying a polypeptide capable of specifically binding to Flt4 receptor tyrosine kinase from the host cell or from the host cell's growth  
30 media.

The invention also is intended to include purified and isolated polypeptide ligands of Flt4 produced by methods of the invention.

In another aspect, the invention includes an antibody which is specifically reactive with polypeptides of the invention, such as an Flt4 receptor tyrosine kinase ligand. Antibodies, both monoclonal and polyclonal, may be made against a ligand of the invention according to standard techniques in the art. Such antibodies may be used in diagnostic applications to monitor angiogenesis, vascularization, lymphatic vessels and their disease states, wound healing, or certain hematopoietic or leukemia cells, or they may be used to block or activate the Flt4 receptor.

Ligands according to the invention may be labeled with a detectable label and used to identify their corresponding receptors *in situ*. Labeled Flt4 ligand and anti-Flt4 ligand antibodies may be used as imaging agents in the detection of lymphatic vessels, high endothelial venules, and Flt4 receptors expressed in histochemical tissue sections. The ligand or antibody may be covalently or non-covalently coupled to a suitable supermagnetic, paramagnetic, electron dense, echogenic, or radioactive agent for imaging. Other, non-radioactive labels, such as biotin and avidin, may also be used.

A related aspect of the invention is a method for the detection of specific cells, *e.g.*, endothelial cells. These cells may be found *in vivo*, or in *ex vivo* biological tissue samples. The method of detection comprises the steps of exposing a biological tissue comprising, *e.g.*, endothelial cells, to a polypeptide according to claim 1, under conditions wherein the polypeptide binds to the cells, optionally washing the biological tissue, and detecting the polypeptide bound to the cells in the biological tissue, thereby detecting the cells.

The present invention also provides diagnostic and clinical applications for claimed ligands. In a preferred embodiment, Flt4 ligands or precursors are used to accelerate angiogenesis, *e.g.*, during wound healing, or to promote the endothelial functions of lymphatic vessels. A utility for VEGF-C is suggested as an inducer of angiogenesis also in tissue transplantation, in eye diseases, in the formation of collateral vessels around arterial stenoses and into injured tissues after infarction. Ligands may be applied in any suitable manner using an appropriate pharmaceutically-acceptable vehicle, *e.g.*, a pharmaceutically-acceptable diluent, adjuvant, excipient or carrier. Ligands also may be used to quantify future metastatic risk by assaying biopsy material for the presence of active receptors or ligands in a binding assay or kit using

detectably-labeled ligand. An Flt4 ligand according to the invention also may be used to promote re-growth or permeability of lymphatic vessels in, for example, organ transplant patients. In addition, an Flt4 ligand may be used to mitigate the loss of axillary lymphatic vessels following surgical interventions in the treatment of cancer (e.g., breast cancer). Ligands according to the invention also may be used to treat or prevent inflammation, edema, aplasia of the lymphatic vessels, lymphatic obstruction, elephantiasis, and Milroy's disease. Finally, Flt4 ligands may be used to stimulate lymphocyte production and maturation, and to promote or inhibit trafficking of leukocytes between tissues and lymphatic vessels or to affect migration in and out of the thymus.

An embodiment of this aspect of the invention is a method of screening for an endothelial cell disorder in a mammalian subject. The method comprises providing a sample of endothelial cells from the subject, contacting the sample of endothelial cells with a polypeptide according to claim 4, determining the growth rate of the cells, and correlating the growth rate with a disorder. In a preferred embodiment, the endothelial cells are lymphatic cells. In another preferred embodiment, the mammalian subject is a human being and the endothelial cells are human cells. In yet another preferred embodiment, the disorder is a vessel disorder, e.g., a lymphatic vessel disorder, such as the loss of lymphatic vessels through surgery or the reduction in function of existing lymphatic vessels due to blockages. In another embodiment, the endothelial cells are contacted with the polypeptide *in vitro*. The growth rate determined in the method is the rate of cell division per unit time, determined by any one of a number of techniques known in the art. The correlation of the growth rate with a disorder can involve a positive or negative correlation, e.g., whether the polypeptide has Flt4 ligand activity or is an inhibitor of such activity, as described below.

Inhibitors of the Flt4 ligand may be used to control endothelial cell proliferation and lymphangiomas. For example, such inhibitors may be used to arrest metastatic growth or spread, or to control other aspects of endothelial cell expression and growth. Inhibitors include antibodies, antisense oligonucleotides, and peptides which block the Flt4 receptor, all of which are intended as aspects of the invention.

In another embodiment, the invention provides a method for modulating the growth of endothelial cells in a mammalian subject comprising

the steps of exposing mammalian endothelial cells to a polypeptide according to the invention in an amount effective to modulate the growth of the mammalian endothelial cells. In one embodiment, the modulation of growth is effected by using a polypeptide capable of stimulating tyrosine phosphorylation of Flt4 receptor tyrosine kinase in a host cell expressing the Flt4 receptor tyrosine kinase. In modulating the growth of endothelial cells, the invention contemplates the modulation of endothelial cell-related disorders. Endothelial cell disorders contemplated by the invention include, but are not limited to, physical loss of lymphatic vessels (*e.g.*, surgical removal of axillary lymph tissue), lymphatic vessel occlusion (*e.g.*, elephantiasis), and lymphangiomas. In a preferred embodiment, the subject, and endothelial cells, are human. The endothelial cells may be provided *in vitro*, or *in vivo*. An effective amount of a polypeptide is defined herein as that amount of polypeptide empirically determined to be necessary to achieve a reproducible change in cell growth rate (as determined by microscopic or macroscopic visualization and estimation of cell doubling time, or nucleic acid synthesis assays), as would be understood by one of ordinary skill in the art.

The present invention also provides methods for using the claimed nucleic acids (*i.e.*, polynucleotides) in screening for endothelial cell disorders. In a preferred embodiment, the invention provides a method for screening an endothelial cell disorder in a mammalian subject comprising the steps of providing a sample of endothelial cell nucleic acids from the subject, contacting the sample of endothelial cell nucleic acids with a polynucleotide according to claim 35, determining the level of hybridization between the endothelial cell nucleic acids and the polynucleotide, and correlating the level of hybridization with a disorder. A preferred mammalian subject, and source of endothelial cell nucleic acids, is a human. The disorders contemplated by the method of screening with polynucleotides include, but are not limited to, vessel disorders such as the aforementioned lymphatic vessel disorders, and hypoxia.

Purified and isolated polynucleotides encoding other (non-human) mammalian VEGF-C forms also are aspects of the invention, as are the polypeptides encoded thereby, and antibodies that are specifically immunoreactive with the non-human VEGF-C variants. Thus, the invention includes a purified and isolated mammalian VEGF-C polypeptide, and also a

purified and isolated polynucleotide encoding such a polypeptide.

In one embodiment, the invention includes a purified and isolated polypeptide having the amino acid sequence of residues 1 to 415 of SEQ ID NO: 41, which sequence corresponds to a putative mouse VEGF-C precursor. The putative mouse VEGF-C precursor is believed to be processed into a mature mouse VEGF-C in a manner analogous to the processing of the human prepro-polypeptide. Thus, in a related aspect, the invention includes a purified and isolated polypeptide capable of specifically binding to an Flt4 receptor tyrosine kinase (*e.g.*, a human or mouse Flt-4 receptor tyrosine kinase), the polypeptide comprising a fragment of the purified and isolated polypeptide having the amino acid sequence of residues 1 to 415 of SEQ ID NO: 41, the fragment being capable of specifically binding to the Flt4 receptor tyrosine kinase. The invention further includes purified and isolated nucleic acids encoding the foregoing polypeptides, such as a nucleic acid comprising all or a portion of the sequence shown in SEQ ID NO: 40.

#### BRIEF DESCRIPTION OF THE DRAWING

Figure 1 is a schematic diagram showing major endothelial cell receptor tyrosine kinases and growth factors involved in vasculogenesis and angiogenesis.

Figure 2 schematically depicts the construction of the pLTRFlt41 expression vector.

Figure 3 schematically depicts the construction of the baculovirus vector encoding a secreted soluble Flt4 extracellular domain (Flt4EC).

Figure 4 shows results of stimulation of Flt4 autophosphorylation by conditioned medium from PC-3 cell cultures.

Figures 5A, 5B, and 5C show that the major tyrosyl phosphorylated polypeptide of Flt4-transfected cells stimulated with PC-3 conditioned medium is the 125 kD Flt4 polypeptide (VEGFR-3), and also that the Flt4 stimulating activity is not adsorbed to heparin-sepharose.

Figure 6 shows Western immunoblotting analysis of the Flt4 ligand activity isolated from PC-3 conditioned medium.

Figure 7 shows results of gel electrophoresis of fractions from the Western analysis of Flt4 ligand (VEGF-C) isolated from PC-3 conditioned

medium.

Figure 8 shows results of Western analysis of Flt4 autophosphorylation induced by either the Flt4 ligand (VEGF-C), VEGF, or PIGF.

5                   Figure 9A schematically depicts the cloning and analysis of the Flt4 ligand, VEGF-C. The VEGF homologous region (dark shaded box) and amino and carboxyl terminal propeptides (light shaded and unshaded boxes, respectively) as well as putative signal sequence (ss) are depicted between 5' and 3' untranslated (ut) nucleic acid regions. The cleavage sites for the signal  
10 sequence and the amino and carboxyl terminal propeptides are indicated with triangles.

                  Figure 9B shows the nucleotide and deduced amino acid sequence of a Flt4 ligand cDNA (without adaptor and poly-A sequences). The cleavage site for the putative amino terminal prepro leader sequence is  
15 indicated with a shaded triangle.

                  Figure 10 shows a comparison of the deduced amino acid sequences of PDGF-A, -B, PIGF-1, VEGF-B<sub>167</sub>, four VEGF isoforms, and Flt4 ligand (VEGF-C).

                  Figure 11 shows the stimulation of autophosphorylation of the  
20 Flt4 receptor by conditioned medium from cells transfected with the pREP7 expression vector containing the VEGF-C-encoding cDNA insert of plasmid FLT4-L.

                  Figure 12 shows Northern blotting analysis of the genes encoding VEGF, VEGF-B, AND VEGF-C (indicated by "FLT4-L") in two  
25 human tumor cell lines.

                  Figure 13A is an autoradiograph showing recombinant VEGF-C isolated following a pulse-chase experiment and electrophoresed via SDS-PAGE under reducing conditions.

                  Figure 13B is a photograph of polyacrylamide gel showing that  
30 recombinant VEGF-C forms are disulfide-linked in nonreducing conditions.

                  Figure 14A and 14B depict Western blots showing that VEGF-C stimulates autophosphorylation of VEGFR-2 (KDR) but has no effect on PDGFR- $\beta$  phosphorylation.

                  Figures 15A and 15B show that VEGF-C stimulates endothelial  
35 cell migration in a three-dimensional collagen gel assay.

Figure 16A shows the expression of VEGF-C mRNA in human adult tissues.

Figure 16B shows the expression of VEGF, VEGF-B, and VEGF-C in selected human fetal tissues.

5           Figure 17 schematically depicts the chromosomal localization of the VEGF-C gene.

Figure 18 is a Northern blot hybridization study showing the effects of hypoxia on the mRNA expression of VEGF (VEGF-A), VEGF-B and VEGF-C.

10           Figure 19 depicts autoradiograms from a pulse-chase immunoprecipitation experiment wherein cells-transfected with a VEGF-C expression vector (VEGF-C) and mock transfected cells (M) were pulse-labeled with radioactive amino acids and chased for varying lengths of time.

15           Figure 20 is a schematic map of the K14-VEGF-C vector construct.

Figures 21A-C depict electrophoretic fractionations of the various forms of recombinant VEGF-C produced by transfected 293 EBNA cells. Figure 21B depicts the electrophoretic fractionation, under non-reducing conditions, of polypeptides produced from mock (M) transfected cells, cells transformed with wild type (wt) VEGF-C cDNA, and cells transfected with a cDNA variant encoding VEGF-C-R102S. Each of the bands identified in Figure 21B was excised and electrophoretically fractionated in a separate lane under reducing conditions. Fractionation of bands corresponding to wt VEGF-C are depicted in Figure 21A; fractionation of bands corresponding to the R102S variant are depicted in Figure 21C.

Figures 22A-B depict the forms and sizes of wild type and mutant recombinant VEGF-Cs, as revealed by non-reducing gel electrophoresis. Figure 22A shows the VEGF-C forms secreted into the media; Figure 22B shows the VEGF-C forms retained by the cells. Mock (M) transfected cells served as a control.

Figures 23A-B present a comparison of the pattern of immunoprecipitated, labelled VEGF-C forms using antisera 882 and antisera 905. Adjacent lanes contain immunoprecipitates that were (lanes marked +) or were not (lanes marked -) subjected to reduction and alkylation.

Figures 24A-B present Northern blots of total RNA isolated from cells grown in the presence or absence of interleukin-1 (IL-1) and/or dexamethasone (DEX) for the indicated times. For Figure 25B, the Northern blot was probed with radiolabeled DNA from a VEGF 581 bp cDNA covering bps 57-638 (Genbank Acc. No. X15997), and a human VEGF-B<sub>167</sub> cDNA fragment (nucleotides 1/382, Genbank Acc. No. U48800). For Figure 24A, the Northern blot was probed with radiolabeled DNA from a human full-length VEGF-C cDNA (Genbank Acc. No. X94216). 18S and 28S- rRNA markers.

Figure 25 illustrates the cloning strategy for inserting a DNA encoding a truncated VEGF-C containing amino acid residues 104-213 into the *Pichia pastoris* expression vector pHIL-S1.

Figures 26A-B show VEGF-C expression in *P. pastoris* cultures transfected with a VEGF-C cDNA, with vector alone, or mock- (M) transfected, following induction with methanol for various periods of time as indicated. About 10  $\mu$ l of medium was analyzed by gel electrophoresis followed by Western blotting and detection with anti-VEGF-C antiserum. Figure 26B depicts the results of a Western blot wherein NIH 3T3 cells expressing VEGFR-3 (Flt4), and PAE cells expressing VEGFR-2 (KDR), were stimulated with 5x concentrated medium from *Pichia* yeast transfected with a VEGF-C cDNA-containing vector (+), with a vector lacking an insert (-), or stimulated with the positive control vanadate. The stimulated cells were lysed and immunoprecipitated with VEGFR-specific antibodies, and the immunoprecipitates were blotted and probed with anti-phosphotyrosine antibodies.

Figures 27A-B present gel electrophoretograms of human VEGF-C (wt) and VEGF-C variants secreted (Figure 27A) or retained (Figure 27B) by the host 293 EBNA cells. Mock (M) transfected cells served as a control. Molecular weight markers are indicated on the left in kilodaltons (kD).

Figures 28A-B show Western blots of VEGFRs that were stimulated to autophosphorylate by wild type (wt) VEGF-C, as well as three VEGF-C polypeptide variants. Cell lysates (NIH 3T3 for VEGFR-3 and PAE for VEGFR-2) were subjected to receptor-specific antisera and the receptors were immunoprecipitated. Immunoprecipitates were then gel-fractionated and blotted for Western analyses. Western blots were probed with anti-

phosphotyrosine antibodies.

Figures 29A-D are photomicrographs of hematoxylin-eosin stained sections of K14-VEGF-C transgenic and control mouse littermate tissues. Areas shown are from the dorsal skin and snout, as indicated. The white arrows show the endothelium-lined margin of the lacunae devoid of red cells.

Figure 30 presents a Northern blot of polyadenylated RNA from the indicated tissues, hybridized with a pool of VEGF, VEGF-B<sub>167</sub>, and VEGF-C probes. Estimated transcript sizes are shown on the right in kilobases (kb).

Figure 31A provides a schematic illustration of the structure of mouse VEGF-C cDNA clones. The human VEGF-C cDNA structure is shown on the top line, with the signal sequence (SS), N-terminal propeptide (N), VEGF- and Balbiani Ring 3 protein (BR3P) homologous regions indicated. The lengths of the 5' and 3' noncoding regions and the long open reading frame are given in base pairs. The "ATG" and "TAA" in Figure 31A indicate the translational start and stop codons, respectively; AAA is the polyadenylation sequence; and Δ is the site of a 12 bp deletion in the mouse cDNA, relative to the human cDNA.

Figure 31B presents a comparison of the human and mouse VEGF-C amino acid sequences. The amino acid sequence of mouse VEGF-C is presented on the top line and differences in the human sequence are marked below it. The sequences have been labeled to depict the regions shown in Figure 32A. The arrow indicates the putative cleavage site for the signal peptidase; BR3P motifs, as well as a CR/SC motif, are boxed; and conserved cysteine residues are marked in bold above the sequence. Arginine residue 158 is also marked in bold. The numbering refers to mouse VEGF-C residues.

Figure 32A presents SDS-PAGE-fractionated samples immunoprecipitated or affinity-purified from various <sup>35</sup>S-labeled media. In the left panel, control medium from Bosc23 cells containing vector only, medium from cells expressing human VEGF-C, and medium from cells expressing mouse VEGF-C were independently precipitated with human VEGFR-3-Extracellular Domain coupled to sepharose. In the right panel, similar conditioned media were subjected to precipitation with anti-VEGF-C

antibodies. mwm: molecular weight markers; m- mouse; h- human;  $\alpha$ - anti.

Figure 32B shows Western blots of gel-fractionated immunoprecipitates from lysates made from NIH 3T3 cells expressing VEGFR-3 that had been stimulated by contact with VEGF-C-containing lysates (or a vector control), as a measure of VEGF-C-induced receptor autophosphorylation. Western blots were probed with anti-phosphotyrosine ( $\alpha$ -PTyr) or anti-receptor antisera (anti-VEGFR-3 and anti-VEGFR-2), as indicated. As a control, receptor autophosphorylation was induced by pervanadate treatment (VO<sub>4</sub>). The arrows and numbers refer to the apparent molecular weights of the tyrosyl phosphorylated receptor polypeptide bands. bVEGF: human baculoviral VEGF-C protein; C-FGEVm: lysate from cells harboring a mouse VEGF-C cDNA cloned into the vector in an antisense orientation.

Figure 33A depicts Northern blots of mRNA isolated from the indicated tissues of adult mice, probed with a VEGF-C probe (top panel), a VEGFR-3 probe (middle panel), and with a pool of the VEGF and VEGF-B probes (lower panel). The sizes of the RNA bands are indicated in kilobases (kb) to the right.

Figure 33B depicts a Northern blot of mouse embryonic mRNA isolated at the indicated gestational ages and probed with a VEGF-C probe.

Figures 34A-D depict photomicrographs of *in situ* hybridizations revealing the expression of VEGF-C and VEGF-B mRNAs in a parasagittal section of a 12.5 day mouse embryo. Figure 34A: VEGF-C probe; j- jugular veins, mn- metanephros, m- mesenterium (arrowheads), vc- intervertebral vessels, lu- lung (arrowheads). Figure 34B: VEGF-B probe; h- heart, nasopharyngeal area (arrowheads). Figure 34C: VEGF-C sense strand probe serving as a control. Figure 34D: bright-field photomicrograph of the same field shown in Figure 34C.

Figures 35A-H depict sections of mouse embryos providing comparisons of VEGF-C and VEGFR-3 expression in the jugular vessels and the mesenteric area. Figures 35A and 35C show expression of VEGF-C transcripts in the mesenchyme around the large sac-like structures in the jugular area (arrowheads). Figures 35B and 35D show expression of VEGFR-3 transcripts in the jugular venous sacs. Figures 35E and 35G show VEGF-C mRNA distribution in the mesenteric region of a 14.5 day p.c. embryo, as

well as around the gut. Figures 35F and 35H show VEGFR-3 mRNA in the mesenteric region of a 14.5 day embryo, as well as the gut area, developing lymphatic vessels, and venules.

Figures 36A-D depict photomicrographs showing FLT4 and VEGF-C *in situ* hybridization of the cephalic region of a 16-day p.c. mouse embryo. A section of the cephalic region hybridized with the Flt4 probe (Figure 36A) shows the developing snout, nasal structures and eyes. A more caudally located section shows hybridization with the VEGF-C probe (Figure 36B). The round structures on both sides in the upper part represent the developing molars. In the upper (dorsal) part on both sides of the midline, the caudal portion of the developing conchae are seen. These structures also are shown in higher magnification darkfield (Figure 36C) and lightfield (Figure 36D) microscopy.

Figure 37 presents a schematic illustration of VEGF-C processing, including the major forms of VEGF-C.

#### DETAILED DESCRIPTION OF THE INVENTION

Described herein is the isolation of a novel vascular endothelial growth factor and the cloning of a DNA encoding this novel growth factor from a cDNA library prepared from the human prostatic adenocarcinoma cell line PC-3. The isolated cDNA encodes a protein which is proteolytically processed and secreted to cell culture medium. The secreted protein, designated VEGF-C, binds to the extracellular domain of Flt4 and induces tyrosine autophosphorylation of Flt4 and VEGFR-2. VEGF-C also stimulates the migration of endothelial cells in collagen gel.

The present invention also is directed to novel growth factor polypeptides which are ligands for the Flt4 receptor tyrosine kinase (VEGFR-3). Ligands of the invention are members of a family of platelet-derived growth factors/vascular endothelial growth factors which promote mitosis and proliferation of vascular endothelial cells and/or mesodermal cells. As described in greater detail in Examples 4 and 5, ligands recognizing the Flt4 receptor tyrosine kinase were purified from a PC-3 prostatic adenocarcinoma cell line (ATCC CRL1435). When applied to a population of cells expressing the Flt4 receptor, ligands of the invention stimulate autophosphorylation, resulting in receptor activation.

A ligand according to the invention may be expressed as a larger precursor which is cleaved to produce the ligand. A coexpressed region in some cases results from alternative splicing of RNA of the ligand gene. Such a co-expressed region may be a function of the particular expression system used to obtain the ligand. The skilled artisan understands that in recombinant production of proteins, additional sequence may be expressed along with a functional peptide depending upon the particular recombinant construct used to express the protein, and subsequently removed to obtain the desired ligand. In some cases the recombinant ligand can be made lacking certain residues of the endogenous/natural ligand. Moreover, it is well-known in that conservative replacements may be made in a protein which do not alter the function of the protein. Accordingly, it is anticipated that such alterations are within the scope of the claims. Moreover, it is anticipated that one or more VEGF-C precursors (the largest putative native secreted VEGF-C precursor having the complete amino acid sequence from residue 32 to residue 419 of SEQ ID NO: 33) is capable of stimulating the Flt4 ligand without any further processing, in a manner similar to that in which VEGF stimulates its receptor in its unprocessed form after the secretion and concomitant release of the signal sequence.

Results reported herein show that Flt4 (VEGFR-3) transmits signals for the VEGF-C novel growth factor. This conclusion is based on the specific binding of VEGF-C to recombinant Flt4EC (Flt4 extracellular domain) protein and the induction of VEGFR-3 autophosphorylation by medium from VEGF-C transfected cells. In contrast, neither VEGF nor PlGF showed specific binding to VEGFR-3 or induced its autophosphorylation.

As set forth in greater detail below, the putative prepro-VEGF-C has a deduced molecular mass of 46,883; a putative prepro-VEGF-C processing intermediate has an observed molecular weight of about 32 kD; and mature VEGF-C isolated from conditioned media has a molecular weight of about 23 kD as assessed by SDS-Page under reducing conditions. A major part of the difference in the observed molecular mass of the purified and recombinant VEGF-C and the deduced molecular mass of the prepro-VEGF-C encoded by the VEGF-C open reading frame (ORF) is attributable to proteolytic removal of sequences at the amino-terminal and carboxyl-terminal regions of the prepro-VEGF-C polypeptide. However, proteolytic cleavage of

the putative 102 amino acid leader sequence is not believed to account for the entire difference between the deduced molecular mass of 46,883 and the observed mass of about 23 kD, because the deduced molecular weight of a polypeptide consisting of amino acids 1-317 of SEQ ID NO: 33 is 35,724 kD. It is believed that a portion of the observed difference in molecular weights is attributable to proteolytic removal of amino acid residues in the amino and carboxyl terminal regions of the VEGF-C precursor. By extrapolation from studies of the structure of PDGF (Heldin *et al.*, *Growth Factors*, 8:245-52 (1993)), it may be that the region critical for receptor binding and activation by VEGF-C is contained within amino acids residues 104-213, which are found in the secreted form of the VEGF-C protein (*i.e.*, the form lacking the putative prepro leader sequence and some carboxyterminal sequences). The 23 kD polypeptide binding VEGFR-3 is likely to represent the VEGF-homologous domain. After biosynthesis, the nascent VEGF-C polypeptide may be glycosylated at three putative N-linked glycosylation sites identified in the deduced VEGF-C amino acid sequence. Polypeptides containing modifications, such as N-linked glycosylations, are intended as aspects of the invention.

The carboxyl terminal amino acid sequences, which increase the length of the VEGF-C polypeptide in comparison with other ligands of this family, show a pattern of spacing of cysteine residues reminiscent of the Balbiani ring 3 protein (BR3P) sequence (Dignam *et al.*, *Gene*, 88:133-40 (1990); Paulsson *et al.*, *J. Mol. Biol.*, 211:331-49 (1990)). This novel C-terminal silk protein-like structural motif of VEGF-C may fold into an independent domain, which, on the basis of the considerations above, is at least partially cleaved off after biosynthesis. Interestingly, at least one cysteine motif of the BR3P type is also found in the carboxyl terminus of VEGF. In our experiments both the putative precursor and cleaved ligand were detected in the cell culture media, although processing was apparently cell-associated on the basis of the pulse-chase experiments. The determination of the amino-terminal and carboxy-terminal sequences of VEGF-C isolates allows the identification of the proteolytic processing sites. The generation of antibodies against different parts of the pro-VEGF-C molecule will allow the exact determination of the precursor-product relationship and ratio, their cellular distribution, and the kinetics of processing and secretion.

VEGF-C has a conserved pattern of eight cysteine residues, which may participate in the formation of intra- and interchain disulfide bonds, creating an antiparallel dimeric biologically active molecule, similar to PDGF. Mutational analysis of the cysteine residues involved in the interchain disulfide bridges has shown that, in contrast to PDGF, VEGF dimers need to be held together by these covalent interactions in order to maintain biological activity. Disulfide linking of the VEGF-C polypeptide chains was evident in the analysis of VEGF-C in nonreducing conditions.

VEGFR-3, which distinguishes between VEGF and VEGF-C, is closely related in structure to VEGFR-1 and VEGFR-2. Finnerty *et al.*, *Oncogene*, 8:2293-98 (1993); Galland *et al.*, *Oncogene*, 8:1233-40 (1993); Pajusola *et al.*, *Cancer Res.*, 52:5738-43 (1992). However, the mature form of VEGFR-3 differs from the two other VEGFRs in that it is proteolytically cleaved in the extracellular domain into two disulfide-linked polypeptides. Pajusola *et al.*, *Oncogene*, 9:3545-55 (1994). Another difference is that 4.5 and 5.8 kb VEGFR-3 mRNAs encode polypeptides differing in their C-termini and apparently in their signalling properties due to the use of alternative 3' exons. Borg *et al.*, *Oncogene*, 10:973-84 (1995); Pajusola *et al.*, *Oncogene*, 8:2931-37 (1993).

Besides VEGFR-3, VEGFR-2 tyrosine kinase also is activated in response to VEGF-C. VEGFR-2 mediated signals cause striking changes in the morphology, actin reorganization and membrane ruffling of porcine aortic endothelial cells overexpressing this receptor. In these cells, VEGFR-2 also mediated ligand-induced chemotaxis and mitogenicity. Waltenberger *et al.*, *J. Biol. Chem.*, 269:26988-95 (1994). Similarly, the receptor chimera CSF-1R/VEGFR-3 was mitogenic when ectopically expressed in NIH 3T3 fibroblastic cells, but not in porcine aortic endothelial cells (Pajusola *et al.*, 1994). Consistent with such results, the bovine capillary endothelial (BCE) cells, which express VEGFR-2 mRNA but very little or no VEGFR-1 or VEGFR-3 mRNAs, showed enhanced migration when stimulated with VEGF-C. Light microscopy of the BCE cell cultures in collagen gel also suggested that VEGF-C stimulated the proliferation of these cells. The data thus indicate that the VEGF ligands and receptors show a great specificity in their signalling, which may be cell-type-dependent.

The expression pattern of the VEGFR-3 (Kaipainen *et al.*, *Proc. Natl. Acad. Sci. (USA)*, 92:3566-70 (1995)) suggests that VEGF-C may function in the formation of the venous and lymphatic vascular systems during embryogenesis. Constitutive expression of VEGF-C in adult tissues shown  
5 herein further suggests that this gene product also is involved in the maintenance of the differentiated functions of the lymphatic endothelium where VEGFR-3 is expressed (Kaipainen *et al.*, 1995). Lymphatic capillaries do not have well-formed basal laminae and an interesting possibility remains that the silk-like BR3P motif is involved in producing a supramolecular structure which  
10 could regulate the availability of VEGF-C in tissues. However, as shown here, VEGF-C also activates VEGFR-2, which is abundant in proliferating endothelial cells of vascular sprouts and branching vessels of embryonic tissues, but not so abundant in adult tissues. Millauer *et al.*, *Nature*, 367:576-78 (1993). These data have suggested that VEGFR-2 is a major regulator of  
15 vasculogenesis and angiogenesis. VEGF-C may thus have a unique effect on lymphatic endothelium and a more redundant function, shared with VEGF, in angiogenesis and possibly in regulating the permeability of several types of endothelia. Because VEGF-C stimulates VEGFR-2 and promotes endothelial migration, VEGF-C may be useful as an inducer of angiogenesis of blood and  
20 lymphatic vessels in wound healing, in tissue transplantation, in eye diseases, and in the formation of collateral vessels around arterial stenoses and into injured tissues after infarction.

Taken together, these results show an increased complexity of signalling in the vascular endothelium. They reinforce the concept that when  
25 organs differentiate and begin to perform their specific functions, the phenotypic heterogeneity of endothelial cells increases in several types of functionally and morphologically distinct vessels. However, upon stimulation by suitable angiogenic stimuli, endothelial cells can re-enter the cell cycle, migrate, withdraw from the cell cycle and subsequently differentiate again to  
30 form new vessels that are functionally adapted to their tissue environment. This process of angiogenesis, concurrent with tissue development and regeneration, depends on the tightly controlled balance between positive and negative signals for endothelial cell proliferation, migration, differentiation and survival.

Previously-identified growth factors promoting angiogenesis include the fibroblast growth factors, hepatocyte growth factor/scatter factor, PDGF and TGF- $\alpha$ . (See e.g., Folkman, *Nature Med.*, 1:27-31 (1995); Friesel *et al.*, *FASEB J.*, 9:919-25 (1995); Mustonen *et al.*, *J. Cell. Biol.*, 129:895-98 (1995). However, VEGF has been the only growth factor relatively specific for endothelial cells. The newly identified factors VEGF-B and VEGF-C thus increase our understanding of the complexity of the specific and redundant positive signals for endothelial cells involved in vasculogenesis, angiogenesis, permeability, and perhaps also other endothelial functions.

Also described herein is the localization of the VEGF-C genes in human chromosomes by analysis of somatic cell hybrids and fluorescence *in situ* hybridization (FISH). Southern blotting and polymerase chain reaction analysis of somatic cell hybrids and fluorescence *in situ* hybridization of metaphase chromosomes were used to assess the chromosomal localization of the VEGF-C gene. The VEGF-C gene was located on chromosome 4q34, close to the human aspartylglucosaminidase gene previously mapped to 4q34-35. The VEGF-C locus at 4q34 is a candidate target for mutations leading to vascular malformations or cardiovascular diseases. Expression studies using Northern blotting show abundant VEGF-C expression in heart and skeletal muscle; other tissues, such as placenta ovary, small intestine, thyroid gland, kidney, prostate, spleen, testis and large intestine also express this gene. Whereas PlGF is predominantly expressed in the placenta, the expression patterns of VEGF, VEGF-B and VEGF-C overlap in many tissues, which suggests that they may form heterodimers and interact to exert their physiological functions.

Targeted mutagenesis leading to inactivation of the VEGF receptor loci in the mouse genome has shown that VEGFR-1 is necessary for the proper organization of endothelial cells forming the vascular endothelium, while VEGFR-2 is necessary for the generation of both endothelial and hematopoietic cells. This suggests that the four genes of the VEGF family can be targets for mutations leading to vascular malformations or cardiovascular diseases.

The following Examples illustrate preferred embodiments of the invention, wherein the isolation, characterization, and function of Flt4 ligands and ligand-encoding nucleic acids according to the invention are shown.

### EXAMPLE 1

#### Production of pLTRFlt4l expression vector

Construction of the LTR-Flt4l vector is schematically shown in Fig. 2. The full-length Flt4s cDNA (Genbank Accession No. X68203, SEQ ID NO: 36) was assembled by first subcloning the S2.5 fragment, reported in Pajusola *et al.*, *Cancer Res.*, 52:5738-5743 (1992), incorporated by reference herein, containing base pairs 56-2534 of the Flt4s into the *EcoRI* site of the pSP73 vector (Promega, Madison, WI).

Since cDNA libraries used for screening of Flt4 cDNAs did not contain the extreme 5' protein-coding sequences, inverse PCR was used for the amplification of the 5' end of Flt4 corresponding to the first 12 amino acid residues (MQRGAALCLRLW). Poly(A)<sup>+</sup> RNA was isolated from human HEL erythroleukemia cells and double-stranded cDNA, were synthesized using an Amersham cDNA Synthesis System Plus kit (Amersham Corp.,

Buckinghamshire, U.K.) and a gene-specific primer: 5'-TGTCCTCGCTGTCCTTGTCT-3' (SEQ ID NO: 1), which was located 195 bp downstream of the 5' end of clone S2.5. Double-stranded cDNA was treated with T4 DNA polymerase to blunt the ends and cDNA was purified by filtration with Centricon 100 filters (Amicon Inc., Beverly, MA).

Circularization of the blunt-ended cDNA was performed by ligation in a total volume of 150 microliters. The reaction mixture contained a standard ligation buffer, 5% PEG-8000, 1 mM DTT and 8 U of T4 DNA ligase (New England Biolabs, Beverly, MA). Ligation was carried out at 16°C for 16 hours.

Fifteen microliters of this reaction mix were used in a standard PCR reaction (100 µl total volume) containing 100 ng of Flt4-specific primers introducing *SacI* and *PstI* restriction sites, and 1 unit of Taq DNA polymerase (Perkin Elmer Cetus). Two rounds of PCR were performed using 33 cycles per round (denaturation at 95°C for 1 minute, annealing at 55°C for 2 minutes, and elongation at 72°C for 4 minutes). The PCR mixture was treated sequentially with the *SacI* and *PstI* restriction enzymes, and after purification with MagicPCR Preps (Promega), DNA fragments were subcloned into the pGEM3Zf(+) vector for sequencing (Promega). The sequence corresponded to the 5' end of the Flt4s cDNA clone deposited in the Genbank Database as Accession No. X68203.

The sequence encoding the first 12 amino acid residues was

added to the expression construct by ligating an *Sph*I-digested PCR fragment amplified using reverse transcription-PCR of poly(A)<sup>+</sup> RNA isolated from the HEL cells. The forward primer had the following sequence: 5'-

ACATGCATGC CACCATGCAG CGGGGCGCCG CGCTGTGCCT

5 CCGACTGTGG CTCTGCCTGG GACTCCTGGA-3' (SEQ ID NO: 2) (*Sph*I site underlined, translational start codon marked in bold). The translation start codon is immediately downstream from an optimized Kozak consensus sequence. Kozak, *Nucl. Acids Res.*, 15: 8125-8148, 1987). The reverse primer, 5'-ACATGCATGC CCCGCCGGT CATCC-3' (SEQ ID NO: 3) (*Sph*I site underlined), to the 5' end of the S2.5 fragment, thus replacing the unique *Sph*I fragment of the S2.5 plasmid. The resulting vector was digested with *Eco*RI and *Cla*I and ligated to a 138 bp PCR fragment amplified from the 0.6 kb *Eco*RI fragment (base pairs 3789 to 4416 in the Genbank X68203 sequence) which encodes the 3' end of Flt4s shown in Figure 1 of Pajusola *et al.*,

15 *Cancer Res.*, 52:5738-5743 (1992), using the oligonucleotides 5'-CGGAATTCCTT CATGACCCCA AC-3' (SEQ ID NO: 4) (forward primer, *Eco*RI site underlined) and 5'-CCATCGATGG ATCCTACCTG AAGCCGCTTT CTT-3' (SEQ ID NO: 5) (reverse primer, *Cla*I site underlined). The coding domain was completed by ligation of the 1.2 kb *Eco*RI fragment (base pairs 2535-3789 of the sequence found in Gen Bank Acc. No. X68203) into the above construct. The complete cDNA was subcloned as a *Hind*III-*Cla*I (blunted) fragment (this *Cla*I site was also included in the 3' primer used to construct the 3' end of the coding sequence) to the pLTRpoly expression vector reported in Mäkelä *et al.*, *Gene*, 118: 293-294 (1992) (Genbank accession number X60280, SEQ ID NO: 37), incorporated by reference herein, using its *Hind*III-*Acc*I (blunted) restriction sites.

The long form of Flt4 was produced by replacing the 3'-end of the short form as follows: The 3' region of the Flt4l cDNA was PCR-amplified using a gene-specific oligonucleotide (SEQ ID NO: 7, see below) and a pGEM 3Z vector-specific (SP6 promoter) oligonucleotide 5'-ATTAGGTGACACTATA-3' (SEQ ID NO: 6) as reverse and forward primers, respectively. The template for PCR was an Flt4l cDNA clone containing a 495 bp *Eco*RI fragment extending downstream of the *Eco*RI site at nucleotide 3789 of the Genbank X68203 sequence (the sequence downstream of this *Eco*RI site is deposited as the Flt4 long form 3' sequence having

Genbank accession number S66407 (SEQ ID NO: 38)). The gene-specific oligonucleotide contains a *Bam*HI restriction site located right after the end of the coding region and has the following sequence: 5'-  
 CCATCGATGGATCCGATGCTGCTTAGTAGCTGT-3' (SEQ ID NO: 7)  
 (*Bam*HI site is underlined). The PCR product was digested with *Eco*RI and *Bam*HI and transferred in frame to the LTRFIt4 vector fragment from which the coding sequences downstream of the *Eco*RI site at base pair 2535 (see sequence X68203) had been removed by *Eco*RI-*Bam*HI digestion. The resulting clone was designated pLTRFIt4. Again, the coding domain was completed by ligation of the 1.2 kb *Eco*RI fragment (base pairs 2535-3789 of sequence X68203) back into the resulting construct.

**EXAMPLE 2**

**Production and analysis of FIt4 transfected cells**

NIH 3T3 cells (60 % confluent) were co-transfected with 5 micrograms of the pLTRFIt4 construct and 0.25 micrograms of the pSV2neo vector containing the neomycin phosphotransferase gene (Southern *et al.*, *J. Mol. Appl. Genet.*, 1:327 (1982)), using the DOTAP liposome-based transfection reagents (Boehringer-Mannheim, Mannheim, Germany). One day after transfection, the cells were transferred into selection media containing 0.5 mg/ml geneticin (GIBCO, Grand Island, N.Y.). Colonies of geneticin-resistant cells were isolated and analyzed for expression of the FIt4 proteins. Cells were lysed in boiling lysis buffer containing 3.3 % SDS 125 mM Tris, pH 6.8. Protein concentrations of the samples were measured by the BCA method (Pierce, Rockford, IL). About 50 micrograms of protein from each lysate were analyzed for the presence of FIt4 by 6 % SDS-polyacrylamide gel electrophoresis (SDS-PAGE) and immunoblotting using antisera against the carboxyl terminus of FIt4. Signals on Western blots were revealed using the ECL method (Amersham).

For production of anti-FIt4 antiserum, the FIt4 cDNA fragment encoding the 40 carboxy-terminal amino acid residues of the short form: NH2-PMTPTTYKGSVDNQDTSQM VLASEEFEQI ESRHRQESGFR-COOH (SEQ ID NO: 8) was cloned as a 657 bp *Eco*RI-fragment into the pGEX-1XT bacterial expression vector (Pharmacia-LKB, Inc., Uppsala, Sweden) in frame

with the glutathione-S-transferase coding region. The resultant GST-Flt4S fusion protein was produced in *E. coli* and purified by affinity chromatography using a glutathione-Sepharose 4B column. The purified protein was lyophilized, dissolved in phosphate-buffered saline (PBS), mixed with Freund's adjuvant and used for immunization of rabbits at bi-weekly intervals using methods standard in the art (Harlow *et al.*, *Antibodies: A Laboratory Manual* (Cold Spring Harbor Laboratory Press, 1988)). Antisera were used, after the fourth booster immunization, for immunoprecipitation of Flt4 from transfected cells. Cell clones expressing Flt4 were also used for ligand stimulation analysis.

### EXAMPLE 3

#### Construction of a Flt4 EC baculovirus vector and expression and purification of its product

The construction of an Flt4 extracellular domain (EC) baculovirus vector is schematically depicted in Fig. 3. The Flt4-encoding cDNA was prepared in both a long form and a short form, each being incorporated in a vector under control of the Moloney murine leukemia virus LTR promoter. The nucleotide sequence of the short form of the Flt4 receptor is available from the Genbank database as Accession No. X68203 and the specific 3' segment of the long form cDNA is available under GenBank Accession No. S66407.

The ends of a cDNA segment encoding the Flt4 extracellular domain (EC) were modified as follows: The 3' end of the Flt4 cDNA sequence (Genbank Accession Number X68203) which encodes the extracellular domain was amplified using primer 1116 (5'-CTGGAGTCGACTTGGCGGACT-3'; SEQ ID NO: 9, *Sa*I site underlined) and primer 1315 (5'-CGCGGATCCCTAGTGATGGTGATGGTGATGTCTACCTTCGATCATGCTGCCCTTAT CCTC-3'; (SEQ ID NO: 10, *Bam*HI site underlined). The sequence at the 5' end of primer 1315 is not complementary to the flt4 coding region. Inspection of the sequence that is complementary to this region of primer 1315 reveals in a 5' to 3' order, a stop codon, six contiguous histidine codons (for subsequent chromatographic purification of the encoded polypeptide using a Nc-NTA column; Qiagen, Hilden, Germany), and an

added *Bam*HI site. The amplified fragment was digested with *Sal*I and *Bam*HI and used to replace a unique *Sal*I-*Bam*HI fragment in the LTRFlt4 vector shown in Fig. 3. The *Sal*I-*Bam*HI fragment that was replaced encodes the Flt4 transmembrane and cytoplasmic domains. The result was a modified LTF Flt4 vector.

The 5' end without the Flt4 signal sequence encoding region was amplified by PCR using the primer 1335 (5'-CCCAAGCTTGGATCCAAGTGGCTACTCCATGACC-3'; (SEQ ID NO: 11) the primer contains added *Hind*III (AAGCTT) and *Bam*HI (GGATCC) restriction sites, which are underlined). The second primer used to amplify the region encoding the Flt4 signal sequence was primer 1332 5'-GTTGCCTGTGATGTGCACCA-3'; SEQ ID NO: 12). The amplified fragment was digested with *Hind*III and *Sph*I (the *Hind*III site (AAGCTT) is underlined in primer 1335 and the *Sph*I site is within the amplified region of the Flt4l cDNA). The resultant *Hind*III-*Sph*I fragment was used to replace a *Hind*III-*Sph*I fragment in the modified LTRFlt4l vector described immediately above (the *Hind*III site is in the 5' junction of the Flt4 insert with the pLTRpoly portion of the vector, the *Sph*I site is in the Flt4 cDNA). The resultant Flt4EC insert was then ligated as a *Bam*HI fragment into the *Bam*HI site in the pVTBac plasmid described in Tessier *et al.*, *Gene* 98:177-183 (1991), incorporated herein by reference. The relative orientation of the insert was confirmed by partial sequencing so that the open reading frame of the signal sequence-encoding portion of the vector was adjacent to, and in frame with, the Flt4 coding region sequence. The Flt4EC construct was transfected together with baculovirus genomic DNA into SF-9 cells by lipofection. Recombinant virus was purified, amplified and used for infection of High-Five cells (Invitrogen, San Diego, CA) using methods standard in the art. The Flt4 extracellular domain (Flt4EC) was purified from the culture medium of the infected High-Five cells using Ni-NTA affinity chromatography according to manufacturer's instructions (Qiagen) for binding and elution of the 6xHis tag encoded in the COOH-terminus of the recombinant Flt4 extracellular domain.

#### EXAMPLE 4

##### Isolation of an Flt4 Ligand from Conditioned Media

A human Flt4 ligand according to the invention was isolated from media conditioned by a PC-3 prostatic adenocarcinoma cell line (ATCC CRL 1435) in Harris F-12 Nutrient mixture (GIBCO) containing 7% fetal calf serum (FCS). The cells were grown according to the supplier's instructions. In order to prepare the conditioned media, confluent PC-3 cells were cultured for 7 days in Ham's F-12 Nutrient mixture (GIBCO) in the absence of fetal bovine serum (FBS). Medium was then cleared by centrifugation at 10,000 g for 20 minutes. The medium was then screened to determine its ability to induce tyrosine phosphorylation of Flt4 by exposure to NIH 3T3 cells which had been transfected with Flt4-encoding cDNA using the pLTRFlt4l vector. For receptor stimulation experiments, subconfluent NIH 3T3 cells were starved overnight in serum-free DMEM medium (GIBCO) containing 0.2% bovine serum albumin (BSA). The cells were stimulated with the conditioned media for 5 minutes, washed twice with cold PBS containing 100 micromolar vanadate, and lysed in RIPA buffer (10 mM Tris pH 7.5, 50 mM NaCl, 0.5% sodium deoxycholate, 0.5% Nonidet P40 (BDH, Poole, England), 0.1% SDS, 0.1 U/ml Aprotinin (Boehringer Mannheim), 1 mM vanadate) for receptor immunoprecipitation analysis. The lysates were centrifuged for 20 minutes at 15,000 x g. The supernatants were incubated for 2 hours on ice with 3 microliters of the antiserum against the Flt4 C-terminus described in Example 2. See also Pajusola *et al.*, *Oncogene*, 8:2931-2937 (1993), incorporated by reference herein.

After a two hour incubation in the presence of anti-Flt4 antiserum, protein A-Sepharose (Pharmacia) was added and incubation was continued for 45 minutes with rotation. The immunoprecipitates were washed three times with the immunoprecipitation buffer and twice with 10 mM Tris, pH 7.5, before analysis by SDS-PAGE. Polypeptides were transferred to nitrocellulose and analyzed by Western blotting using Flt4- or phosphotyrosine-specific antisera and the ECL method (Amersham Corp.). Anti-phosphotyrosine monoclonal antibodies (anti-PTyr; PY20) were purchased from Transduction Laboratories (Lexington, Kentucky). In some cases, the filters were restained with a second antibody after stripping. The stripping of the filters was done for 30 minutes at 50°C in 100 mM 2-mercaptoethanol; 2%

SDS, 62.5 mM Tris-HCl pH 6.7 with occasional agitation.

As shown in Fig. 4, the PC-3 conditioned medium stimulated tyrosine phosphorylation of a 125 kD polypeptide when Flt4- expressing NIH 3T3 cells were treated with the indicated preparations of media, lysed, and the lysates were immunoprecipitated with anti-Flt4 antiserum followed by SDS-PAGE, Western blotting, and staining using anti-PTyr antibodies. The resulting band was weakly phosphorylated upon stimulation with unconcentrated PC-3 conditioned medium (lane 2). The 125 kD band comigrated with the tyrosine phosphorylated, processed form of the mature Flt4 from pervanadate-treated cells (compare lanes 2 and 7 of Fig. 4, see also Fig. 5A). Comigration was confirmed upon restaining with anti-Flt4 antibodies as is also shown in Fig. 5A (panel on the right). In order to show that the 125 kD polypeptide is not a non-specific component of the conditioned medium reactive with anti-phosphotyrosine antibodies, 15 microliters of conditioned medium were separated by SDS-PAGE, blotted on nitrocellulose, and the blot was stained with anti-PTyr antibodies. No signal was obtained (Fig. 5B). Also, unconditioned medium failed to stimulate Flt4 phosphorylation, as shown in Fig. 4, lane 1.

Fig. 5C shows a comparison of the effects of PC-3 CM stimulation (+) on untransfected (lanes 4 and 5), FGFR-4-transfected (lanes 8 and 9) and Flt4-transfected NIH 3T3 cells (lanes 1-3, 6 and 7). These results indicate that neither untransfected NIH 3T3 cells nor NIH 3T3 cells transfected with FGFR-4 showed tyrosine phosphorylation of a protein of about 125 kD upon stimulation with the conditioned medium from PC-3 cells. Analysis of stimulation by PC-3 CM pretreated with Heparin-Sepharose CL-6B (Pharmacia) for 2 hours at room temperature (lane 3) showed that the Flt4 ligand does not bind to heparin.

As shown in Fig. 4, lane 3, stimulating activity was considerably increased when the PC-3 conditioned medium was concentrated four-fold using a Centricon-10 concentrator (Amicon). Fig. 4, lane 4, shows that pretreatment of the concentrated PC-3 conditioned medium with 50 microliters of the Flt4 extracellular domain coupled to CNBr-activated sepharose CL-4B (Pharmacia; about 1mg of Flt4EC domain/ml sepharose resin) completely abolished Flt4 tyrosine phosphorylation. Similar pretreatment of the conditioned medium with unsubstituted sepharose CL-4B

did not affect stimulatory activity, as shown in Fig. 4, lane 5. Also, the flow through obtained after concentration, which contained proteins of less than 10,000 molecular weight, did not stimulate Flt4 phosphorylation, as shown in Fig. 4, lane 6.

5                    In another experiment, a comparison of Flt4 autophosphorylation in transformed NIH 3T3 cells expressing LTRFlt4l was conducted, using unconditioned medium, medium from PC-3 cells expressing the Flt4 ligand, or unconditioned medium containing either 50 ng/ml of VEGF165 or 50 ng/ml of PlGF-1. The cells were lysed, immunoprecipitated  
10                   using anti-Flt4 antiserum and analyzed by Western blotting using anti-phosphotyrosine antibodies. As shown in Fig. 8, only the PC-3 conditioned medium expressing the Flt4 ligand (lane Flt-4L) stimulated Flt4 autophosphorylation.

                    The foregoing data show that PC-3 cells produce a ligand which  
15                   binds to the extracellular domain of Flt4 and activates this receptor.

#### EXAMPLE 5

##### Purification of the Flt4 Ligand

                    The ligand expressed by human PC-3 cells as characterized in Example 3 was purified and isolated using a recombinantly-produced Flt4  
20                   extracellular domain (Flt4EC) in affinity chromatography.

                    Two harvests of serum-free conditioned medium, comprising a total of 8 liters, were collected from 500 confluent 15 cm diameter culture dishes containing confluent layers of PC-3 cells. The conditioned medium was clarified by centrifugation at 10,000 x g and concentrated 80-fold using an  
25                   Ultrasette Tangential Flow Device (Filtron, Northborough, MA) with a 10 kD cutoff Omega Ultrafiltration membrane according to the manufacturer's instructions. Recombinant Flt4 extracellular domain was expressed in a recombinant baculovirus cell system and purified by affinity chromatography on Ni-agarose (Ni-NTA affinity column obtained from Qiagen). The purified  
30                   extracellular domain was coupled to CNBr-activated Sepharose CL-4B at a concentration of 5 mg/ml and used as an affinity matrix for ligand affinity chromatography.

                    Concentrated conditioned medium was incubated with 2 ml of the recombinant Flt4 extracellular domain-Sepharose affinity matrix in a

rolling tube at room temperature for 3 hours. All subsequent purification steps were at +4 °C. The affinity matrix was then transferred to a column with an inner diameter of 15 mm and washed successively with 100 ml of PBS and 50 ml of 10 mM Na-phosphate buffer (pH 6.8). Bound material was eluted step-  
5 wise with 100 mM glycine-HCl, successive 6 ml elutions having pHs of 4.0, 2.4, and 1.9. Several 2 ml fractions of the eluate were collected in tubes containing 0.5 ml 1 M Na-phosphate (pH 8.0). Fractions were mixed immediately and dialyzed in 1 mM Tris-HCl (pH 7.5). Aliquots of 75 µl each were analyzed for their ability to stimulate tyrosine phosphorylation of Flt4.  
10 The ultrafiltrate, 100 µl aliquots of the concentrated conditioned medium before and after ligand affinity chromatography, as well as 15-fold concentrated fractions of material released from the Flt4 extracellular domain-Sephacrose matrix during the washings were also analyzed for their ability to stimulate Flt4 tyrosine phosphorylation.

15 As shown in Fig. 6, lane 3, the concentrated conditioned medium induced prominent tyrosine phosphorylation of Flt4 in transfected NIH 3T3 cells overexpressing Flt4. This activity was not observed in conditioned medium taken after medium was exposed to the Flt4 Sepharose affinity matrix described above (Fig. 6, lane 4). The specifically-bound Flt4-  
20 stimulating material was retained on the affinity matrix after washing in PBS, 10 mM Na-phosphate buffer (pH 6.8), and at pH 4.0 (Fig. 6, lanes 5-7, respectively), and it was eluted in the first two 2 ml aliquots at pH 2.4 (lanes 8 and 9). A further decrease of the pH of the elution buffer did not cause release of additional Flt4-stimulating material (Fig. 6, lane 11). Fig. 6, lane 1  
25 depicts a control wherein Flt4-expressing cells were treated with unconditioned medium; lane 2 depicts the results following treatment of Flt4-expressing cells with the ultrafiltrate fraction of conditioned medium containing polypeptides of less than 10 kD molecular weight.

Small aliquots of the chromatographic fractions were  
30 concentrated in a SpeedVac concentrator (Savant, Farmingdale, N.Y.) and subjected to SDS-PAGE under reducing conditions with subsequent silver staining of the gel a standard technique in the art. As shown in Fig. 7, the major polypeptide, having a molecular weight of approximately 23 kD (reducing conditions), was detected in the fractions containing Flt4 stimulating  
35 activity (corresponding to lanes 8 and 9 in Fig. 6). That polypeptide was not

found in the other chromatographic fractions. On the other hand, all other components detected in the two active fractions were also distributed in the starting material and in small amounts in the other washing and eluting steps after their concentration. Similar results were obtained in three independent affinity purifications, indicating that the 23 kD polypeptide specifically binds to Flt4 and induces tyrosine phosphorylation of Flt4.

Fractions containing the 23 kD polypeptide were combined, dried in a SpeedVac concentrator and subjected to SDS-PAGE in a 12.5% gel. The proteins from the gel were then electroblotted to Immobilon-P (PVDF) transfer membrane (Millipore, Marlborough, MA) and visualized by staining of the blot with Coomassie Blue R-250. The region containing only the stained 23 kD band was cut from the blot and subjected to N-terminal amino acid sequence analysis in a Prosite Protein Sequencing System (Applied Biosystems, Foster City, CA). The data were analyzed using a 610A Data Analysis System (Applied Biosystems). Analysis revealed a single N-terminal sequence of NH<sub>2</sub>-XEETKFAAAHYNTEILK-COOH (SEQ ID NO: 13).

#### EXAMPLE 6

##### Construction of PC-3 cell cDNA library in a eukaryotic expression vector

Human poly(A)<sup>+</sup> RNA was isolated from five 15 cm diameter dishes of confluent PC-3 cells by a single step method using oligo(dT) (Type III, Collaborative Biomedical Products, Becton-Dickinson Labware, Bedford, MA) cellulose affinity chromatography (Sambrook *et al.*, 1989). The yield was 70 micrograms. Six micrograms of the Poly(A)<sup>+</sup> RNA were used to prepare an oligo(dT)-primed cDNA library in the mammalian expression vector pcDNA I and the Librarian kit of Invitrogen according to the instructions included in the kit. The library was estimated to contain about 10<sup>6</sup> independent recombinants with an average insert size of approximately 1.8 kb.

### EXAMPLE 7

#### Amplification of the unique nucleotide sequence encoding the Flt4 ligand

5 Degenerate oligonucleotides were designed based on the N-terminal amino acid sequence of the isolated human Flt4 ligand and were used as primers in a polymerase chain reaction (PCR) to amplify cDNA encoding the Flt4 ligand from a PC-3 cell library. The overall strategy is schematically depicted in Fig. 9A, where the different primers have been marked with arrows.

10 The PCR was carried out using 1 microgram of DNA from the amplified PC-3 cDNA library and a mixture of 48 sense-strand primers present in equal proportions, the primer sequences collectively comprising the sequence 5'-GCAGARGARACNATHAA-3' (SEQ ID NO: 14) (wherein R is A or G, N is A, G, C or T and H is A, C or T), encoding amino acid residues  
15 2-6 (EETIK, SEQ ID NO: 15) and 384 antisense-strand primers present in equal proportions, the anti-sense strand primers collectively comprising the sequence 5'-GCAYTTNARDATYTCNGT-3' (SEQ ID NO: 16) (wherein Y is C or T and D is A, G or T), corresponding to amino acid residues 14-18 (TEILK, SEQ ID NO: 17). Three extra nucleotides (GCA) were added to the  
20 5'-terminus of each primer to increase annealing stability. Two successive PCR runs were carried out using 1 U per reaction of DynaZyme (F-500L, Finnzymes, Espoo, Finland)\*, a thermostable DNA polymerase, in a buffer supplied by the manufacturer (10 mM Tris-HCl, pH 8.8 at 25°C, 1.5 mM MgCl<sub>2</sub>, 50 mM KCl, 0.1% Triton-X100), at an extension temperature of 72°C.  
25 The first PCR run was carried out for 43 cycles. The first three cycles were run at an annealing temperature of 33°C for 2 minutes, and the remaining cycles were run at 42°C for 1 minute.

The region of the gel containing a weak band of the expected size (57 bp) was cut out from the gel and eluted. The eluted material was  
30 reamplified for 30 cycles using the same primer pairs described above at 42°C for 1 minute. The amplified fragment was cloned into a pCR II vector (Invitrogen) using the TA cloning kit (Invitrogen) and sequenced using the radioactive dideoxynucleotide sequencing method of Sanger. Six clones were analyzed and all six clones contained the sequence encoding the expected

peptide (amino acid residues 104-120 of the Flt4 ligand precursor). Nucleotide sequence spanning the region from the third nucleotide of codon 6 to the third nucleotide of codon 13 (the extension region) was identical in all six clones: 5'-ATTCGCTGCAGCACACTACAAC-3' (SEQ ID NO: 18) and thus  
5 represented an amplified product from the unique sequence encoding part of the amino terminus of the Flt4 ligand.

#### EXAMPLE 8

##### Amplification of the 5'-end of the cDNA encoding the Flt4 ligand

10 Based on the unique nucleotide sequence encoding the N-terminus of the isolated human Flt4 ligand, two pairs of nested primers were designed to amplify, in two nested PCR reactions, the complete 5'-end of the corresponding cDNAs from one microgram of DNA of the above-described PC-3 cDNA library. First, amplification was performed with an equal mixture  
15 of 4 primers collectively defining the sequence 5'-TCNGTGTGTAGTGTGCTG-3' (SEQ ID NO: 19), which is the antisense-strand primer corresponding to amino acid residues 9-15 (AAHYNTE, SEQ ID NO: 20), and sense-strand primer 5'-TAATACGACTCACTATAGGG-3' (SEQ ID NO: 21), corresponding to the T7 RNA promoter of the pcDNA1  
20 vector used for construction of the library. "Touchdown" PCR was used as disclosed in Don *et al.*, *Nucl. Acids Res.*, 19:4008 (1991), incorporated by reference herein. The annealing temperature of the two first cycles was 62°C and subsequently the annealing temperature was decreased in every other cycle by 1°C until a final temperature of 53°C was reached, at which temperature  
25 additional cycles were conducted. Annealing time was 1 minute and extension at each cycle was conducted at 72°C for 1 minute. Multiple amplified DNA fragments were obtained in the first reaction. The products of the first amplification (1 µl of a 1:100 dilution in water) were used in the second amplification reaction employing a pair of nested primers comprising an  
30 antisense-strand primer 5'-GTTGTAGTGTGCTGCAGCGAATTT-3'; SEQ ID NO: 22) encoding amino acid residues 6-13 (KFAAAHYN, SEQ ID NO: 23) of the Flt4 ligand, and a sense-strand primer (5'-TCACTATAGGGAGACCCAAGC-3'; SEQ ID NO: 24), corresponding to

nucleotides 2179-2199 of the pcDNAI vector. The sequences of these sense and antisense primers overlapped with the 3' ends of the corresponding primers used in the first PCR. "Touchdown" PCR was carried out by decreasing the annealing temperature from 72°C to 66°C and continuing with 18 additional cycles at 66°C. The annealing time was 1 minute and extension at each cycle was carried out at 72°C for 2 minutes. One major product of about 220 bp and three minor products of about 270 bp, 150 bp, and 100 bp were obtained.

The amplified fragment of approximately 220 bp was excised from an agarose gel, cloned into a pCRII vector using the TA cloning kit (Invitrogen); and sequenced. Three recombinant clones were analyzed and they contained the sequence 5'-

TCACTATAGGGAGACCCAAGCTTGGTACCGAGCTCGGATCCACTAGT  
AACGGCCGCCAGTGTGGTGAATTCGACGAAGTCACTGACTGTACTCT  
ACCCAGAATATTGGAAAATGTACAAGTGTGCTAGCTAAGGCAAGGAGGC  
TGGCAACATAACAGAGAACAGGCCAACCTCAACTCAAGGACAGAAG  
AGACTATAAAATTCGCTGCAGCACACTACAAC- 3' (SEQ ID NO: 25).

The beginning of the sequence represents the pcDNAI vector and the underlined sequence represents the amplified product of the 5'-end of the insert.

#### EXAMPLE 9

##### Amplification of the 3'-end of cDNA encoding the Flt4 ligand

Based upon the amplified 5'-sequence of the clones encoding the amino terminus of the 23 kD human Flt4 ligand, two pairs of non-overlapping nested primers were designed to amplify the 3'-portion of the Flt-4-ligand-encoding cDNA clones. The sense-strand primer 5'-ACAGAGAACAGGCCAACC-3' (SEQ ID NO: 26), corresponding to nucleotides 152-169 of the amplified 5'-sequences of the Flt4 ligand (SEQ ID NO: 25), and antisense-strand primer 5'-TCTAGCATTTAGGTGACAC-3' (SEQ ID NO: 27) corresponding to nucleotides 2311-2329 of the pcDNAI vector were used in a first "touchdown" PCR. The annealing temperature of the reaction was decreased 1°C every two cycles from 72°C to 52°C, at which temperature 15 additional cycles were carried out. The annealing time was 1 minute and extension at each cycle was carried out at 72°C for 3 minutes.

DNA fragments of several sizes were obtained in the first amplification. Those products were diluted 1:200 in water and reamplified in PCR using the second pair of primers: 5'-AAGAGACTATAAAATTCGCTGCAGC-3' (SEQ ID NO: 28) and 5'-CCCTCTAGATGCATGCTCGA-3' (SEQ ID NO: 29) (antisense-strand primer corresponding to nucleotides 2279-2298 of the pcDNAI vector). Two DNA fragments were obtained, having sizes of 1350 bp and 570 bp. Those fragments were cloned into a pCRII vector and the inserts of the clones were sequenced. Both of these fragments were found to contain sequences encoding an amino acid sequence homologous to the VEGF sequence.

#### EXAMPLE 10

##### Screening the PC-3 cell cDNA library using the 5' PCR fragment of Flt4 ligand cDNA

A 219 bp 5'-terminal fragment of human Flt4 ligand cDNA was amplified by PCR using the 5' PCR fragment described above and primers 5'-GTGTAGTGTGCTGCAGCGAATTT-3' (antisense-strand primer, SEQ ID NO: 30) and 5'-TCACTATAGGGAGACCCAAGC-3' (SEQ ID NO: 31) (sense-primer corresponding to nucleotides 2179-2199 of the pcDNAI vector). The amplified product was subjected to digestion with *EcoRI* (Boehringer Mannheim) to remove the portion of the DNA sequence amplified from the pcDNAI vector and the resulting 153 bp fragment encoding the 5' end of the Flt4 ligand was labeled with [<sup>32</sup>P]-dCTP using the Klenow fragment of *E. coli* DNA polymerase I (Boehringer Mannheim). That fragment was used as a probe for hybridization screening of the amplified PC-3 cell cDNA library.

Filter replicas of the library were hybridized with the radioactively labeled probe at 42°C for 20 hours in a solution containing 50% formamide, 5x SSPE, 5x Denhardt's solution, 0.1% SDS and 0.1 mg/ml denatured salmon sperm DNA. Filters were washed twice in 1x SSC, 0.1% SDS for 30 minutes at room temperature, then twice for 30 minutes at 65°C and exposed overnight.

On the basis of autoradiography, 10 positive recombinant bacterial colonies hybridizing with the probe were chosen from the library. Plasmid DNA was purified from these colonies and analyzed by *EcoRI* and

*NorI* digestion and agarose gel electrophoresis followed by ethidium bromide staining. The ten plasmid clones were divided into three groups on the basis of the presence of insert sizes of approximately 1.7, 1.9 and 2.1 kb, respectively. Inserts of plasmids from each group were sequenced using the T7 oligonucleotide as a primer and walking primers for subsequent sequencing reactions.

Sequence analysis showed that all clones contain the open reading frame encoding the NH<sub>2</sub>-terminal sequence of the 23 kD human Flt4 ligand. Dideoxy sequencing was continued using walking primers in the downstream direction. A complete human cDNA sequence and deduced amino acid sequence from a 2.1 kb clone is set forth in Fig. 9B (SEQ ID NOs: 32 and 33, respectively). A putative cleavage site of a "prepro" leader sequence is indicated in Fig. 9B with a shaded triangle. When compared with sequences in the GenBank Database, the predicted protein product of this reading frame was found to be homologous with the predicted amino acid sequences of the PDGF/VEGF family of growth factors, as shown in Fig. 10.

Plasmid pFLT4-L, containing the 2.1 kb human cDNA clone in pcDNA1 vector, has been deposited with the American Type Culture Collection, 12301 Parklawn Drive, Rockville, MD 20852 as accession number 97231.

#### EXAMPLE 11

##### Stimulation of Flt4 autophosphorylation by the protein product of the Flt4 ligand vector

The 2.1 kb human cDNA insert of plasmid pFlt4-L, which contains the open reading frame encoding the sequence shown in Fig. 9B (SEQ ID NO: 32; human VEGF-C, see below), was cut out from the pcDNA1 vector using *HindIII* and *NorI* restriction enzymes, isolated from a preparative agarose gel, and ligated to the corresponding sites in the pREP7 expression vector (Invitrogen). The pREP7 vector containing the pFlt4-L insert was transfected into 293-EBNA cells (Invitrogen) using the calcium phosphate transfection method (Sambrook *et al.*, 1989). About 48 hours after transfection the medium of the transfected cells was changed to DMEM medium lacking fetal calf serum and incubated for 36 h. The conditioned medium was then

collected, centrifuged at 5000 x g for 20 minutes, the supernatant was concentrated 5-fold using Centriprep 10 (Amicon) and used to stimulate NIH 3T3 cells expressing LTRFlt4l (the Flt4 receptor), as in Example 4. The cells were lysed, immunoprecipitated using anti-Flt4 antiserum and analyzed by Western blotting using anti-phosphotyrosine antibodies.

As can be seen from Fig. 11, lanes 1 and 3, the conditioned medium from two different dishes of the transfected cells stimulated Flt4 autophosphorylation in comparison with the medium from mock-transfected cells, which gave only background levels of phosphorylation of the Flt4 receptor (lane 2). When the concentrated conditioned medium was pre-absorbed with 20 microliters of a slurry of Flt4<sub>EC</sub> domain coupled to Sepharose (see example 4), no phosphorylation was obtained (lane 4), showing that the activity responsible for Flt4 autophosphorylation was indeed the Flt4 ligand. Thus, these results demonstrate that an expression vector having an approximately 2.1 kb insert and containing an open reading frame as shown in Fig. 9B (and SEQ ID NO: 32) is expressed as a biologically active Flt4 ligand (VEGF-C) in transfected cells. The sequence encoded by that open reading frame is shown in SEQ ID NO: 33.

The deduced molecular weight of a polypeptide consisting of the complete amino acid sequence in Fig. 9B (SEQ ID NO: 33, residues 1 to 419) is 46,883. The deduced molecular weight of a polypeptide consisting of amino acid residues 103 to 419 of SEQ ID NO: 33 is 35,724. The Flt4 ligand purified from PC-3 cultures had an observed molecular weight of about 23 kD as assessed by SDS-PAGE under reducing conditions. Thus, it appears that the Flt4 ligand mRNA is translated into a precursor polypeptide, from which the mature ligand is derived by proteolytic cleavage. Also, the Flt4 ligand may be glycosylated at three putative N-linked glycosylation sites conforming to the consensus which can be identified in the deduced Flt4 ligand amino acid sequence (N-residues underlined in Fig. 10).

The carboxyl terminal amino acid sequences, which increase the predicted molecular weight of the Flt4 ligand subunit in comparison with other ligands of this family, show a pattern of spacing of cysteine residues reminiscent of the Baibiani ring protein 3 (BR3P) sequence (Dignam *et al.*, *Gene*, 88:133-140 (1990)), as depicted schematically in Fig. 9A. Such a sequence may encode an independently folded domain present in a Flt4 ligand

precursor and it may be involved, for example, in the regulation of secretion, solubility, stability, cell surface localization or activity of the Flt4 ligand. Interestingly, at least one cysteine motif of the BR3P type is also found in the VEGF carboxy terminal amino acid sequences.

5           Thus, the Flt4 ligand mRNA appears first to be translated into a precursor from the mRNA corresponding to the cDNA insert of plasmid FLT4-L, from which the mature ligand is derived by proteolytic cleavage. To define the mature Flt4 ligand polypeptide, one first expresses the cDNA clone (which is deposited in the pcDNA1 expression vector) in cells, such as COS  
10   cells. One uses antibodies generated against encoded peptides, fragments thereof, or bacterial Flt4 fusion proteins, such as a GST-fusion protein, to raise antibodies against the VEGF-homologous domain and the amino- and carboxyl-terminal propeptides of Flt4 ligand. One then follows the biosynthesis and processing of the Flt4 ligand in the transfected cells by pulse-  
15   chase analysis using radioactive cysteine for labelling of the cells, immunoprecipitation and gel electrophoresis. Using antibodies against the three domains of the product encoded by the cDNA insert of plasmid FLT4-L, material for radioactive or nonradioactive amino-terminal sequence analysis is isolated. The determination of the amino-terminal sequence of the mature  
20   VEGF-C polypeptide allows for identification of the amino-terminal proteolytic processing site. The determination of the amino-terminal sequence of the carboxyl-terminal propeptide will give the carboxyl-terminal processing site. This is confirmed by site-directed mutagenesis of the amino acid residues adjacent to the cleavage sites, which would prevent the cleavage.

25           On the other hand, the Flt4 ligand is characterized by progressive 3' deletions in the 3' coding sequences of the Flt4 ligand precursor clone, introducing a stop codon resulting in carboxy-terminal truncations of its protein product. The activities of such truncated forms are assayed by, for example, studying Flt4 autophosphorylation induced by the truncated proteins  
30   when applied to cultures of cells, such as NIH 3T3 cells expressing LTRFlt4. By extrapolation from studies of the structure of the related platelet derived growth factor (PDGF, Heldin *et al.*, *Growth Factors*, 8:245-252 (1993)) one determines that the region critical for receptor activation by the Flt4 ligand is contained within its first approximately 180 amino acid residues of the secreted  
35   VEGF-C protein lacking the putative 102 amino acid prepro leader, and

apparently within the first approximately 120 amino acid residues.

On the other hand, the difference between the molecular weights observed for the purified ligand and deduced from the open reading frame of the Flt4 precursor clone may be due to the fact that the soluble ligand was produced from an alternatively spliced mRNA which would also be present in the PC-3 cells, from which the isolated ligand was derived. To isolate such alternative cDNA clones one uses cDNA fragments of the deposited clone and PCR primers made according to the sequence provided as well as techniques standard in the art to isolate or amplify alternative cDNAs from the PC-3 cell cDNA library. One may also amplify using reverse transcription (RT)-PCR directly from the PC-3 mRNA using the primers provided in the sequence of the cDNA insert of plasmid FLT4-L. Alternative cDNA sequences are determined from the resulting cDNA clones. One can also isolate genomic clones corresponding to the Flt4 ligand mRNA transcript from a human genomic DNA library using methods standard in the art and to sequence such clones or their subcloned fragments to reveal the corresponding exons. Alternative exons can then be identified by a number of methods standard in the art, such as heteroduplex analysis of cDNA and genomic DNA, which are subsequently characterized.

## EXAMPLE 12

### Expression of the Gene Encoding VEGF-C in Human Tumor Cell Lines

Expression of transcripts corresponding to the Flt4 ligand (VEGF-C) was analyzed by hybridization of Northern blots containing isolated poly(A)<sup>+</sup> RNA from HT-1080 and PC-3 human tumor cell lines. The probe was the radioactively labelled insert of the 2.1 kb cDNA clone (pFlt4-L/VEGF-C) specific activity  $10^8$ - $10^9$  cpm/mg of DNA). The blot was hybridized overnight at 42°C using 50% formamide, 5 x SSPE buffer, 2% SDS, 10 x Denhardt's solution, 100 mg/ml salmon sperm DNA and  $1 \times 10^6$  cpm of the labelled probe/ml. The blot was washed at room temperature for 2 x 30 minutes in 2 x SSC containing 0.05% SDS, and then for 2 x 20 min at 52°C in 0.1 x SSC containing 0.1% SDS. The blot was then exposed at -70°C

for three days using intensifying screens and Kodak XAR film. Both cell lines expressed an Flt4 ligand mRNA of about 2.4 kb, as well as VEGF and VEGF-B mRNAs (Fig. 12).

### EXAMPLE 13

#### 5                    VEGF-C Chains Are Proteolytically Processed                          after Biosynthesis and Disulfide Linked

The predicted molecular mass of a secreted human VEGF-C polypeptide, as deduced from the VEGF-C open reading frame, is 46,883 kD, suggesting that VEGF-C mRNA may be first translated into a precursor, from  
10        which the ligands of 21/23 kD and 29/32 kD are derived by proteolytic cleavage.

This possibility was explored by metabolic labelling of 293 EBNA cells expressing VEGF-C. Initially, 293 EBNA cells were transfected with the VEGF-C construct. Expression products were labeled by the addition  
15        of 100  $\mu$ Ci/ml of Pro-mix<sup>TM</sup> L-[<sup>35</sup>S] *in vitro* cell labelling mix (Amersham) to the culture medium devoid of cysteine and methionine. After two hours, the cell layers were washed twice with PBS and the medium was then replaced with DMEM-0.2% BSA. After 1, 3, 6, 12 and 24 hours of subsequent incubation, the culture medium was collected, clarified by centrifugation, and  
20        concentrated, and human VEGF-C was bound to 30  $\mu$ l of a slurry of Flt4EC-Sepharose overnight at +4°C, followed by three washes in PBS, two washes in 20 mM Tris-HCl (pH 7.5), alkylation, SDS-PAGE and autoradiography. Alkylation was carried out by treatment of the samples with 10mM 1,4 Dithiothreitol (Boehringer-Mannheim, Mannheim, Germany) for  
25        one hour at 25°C, and subsequently with 30 mM iodoacetamide (Fluka, Buchs, Switzerland).

These experiments demonstrated that a putative precursor polypeptide of 32 kD apparent molecular mass was bound to the Flt4EC affinity matrix from the conditioned medium of metabolically labelled cells  
30        transfected with a human VEGF-C expression vector (Fig. 13A). Increased amounts of a 23 kD receptor binding polypeptide accumulated in the culture medium during a subsequent chase period of three hours, but not thereafter (lanes 2-4 and data not shown), suggesting that the 23 kD form is produced by proteolytic processing, which is cell-associated and incomplete, at least in the

transiently transfected cells. The arrows in Fig. 13A indicate the 32 kD and 23 kD polypeptides of secreted VEGF-C. Subsequent experiments showed that the 32kD VEGF-C form contains two components migrating in the absence of alkylation as polypeptides of 29 and 32 kD (Figs. 21-23).

5 In a related experiment, human VEGF-C isolated using Flt4EC-Sepharose after a 4 h continuous metabolic labelling was analyzed by polyacrylamide gel electrophoresis in nonreducing conditions (Fig. 13B). Higher molecular mass forms were observed under nonreducing conditions, suggesting that the VEGF-C polypeptides can form disulfide-linked dimers and/or multimers (arrows in Fig. 13B).  
10

#### EXAMPLE 14

##### Stimulation Of VEGFR-2 Autophosphorylation By VEGF-C

Conditioned medium (CM) from 293 EBNA cells transfected with the human VEGF-C vector also was used to stimulate porcine aortic  
15 endothelial (PAE) cells expressing VEGFR-2. Pajusola *et al.*, *Oncogene*, 9:3545-55 (1994); Waltenberger *et al.*, *J. Biol. Chem.*, 269:26988-26995 (1994). The cells were lysed and immunoprecipitated using VEGFR-2 - specific antiserum (Waltenberger *et al.*, 1994).

PAE-KDR cells (Waltenberger *et al.*, 1994) were grown in  
20 Ham's F12 medium-10% fetal calf serum (FCS). Confluent NIH 3T3-Flt4 cells or PAE-KDR cells were starved overnight in DMEM or Ham's F12 medium, respectively, supplemented with 0.2% bovine serum albumin (BSA), and then incubated for 5 min with the analyzed media. Recombinant human VEGF (R&D Systems) and PDGF-BB, functional as stimulating agents, were  
25 used as controls. The cells were washed twice with ice-cold Tris-Buffered Saline (TBS) containing 100 mM sodium orthovanadate and lysed in RIPA buffer containing 1 mM phenylmethylsulfonyl fluoride (PMSF), 0.1 U/ml aprotinin and 1 mM sodium orthovanadate. The lysates were sonicated, clarified by centrifugation at 16,000 x g for 20 min and incubated for 3-6 h on  
30 ice with 3-5  $\mu$ l of antisera specific for Flt4 (Pajusola *et al.*, 1993), VEGFR-2 or PDGFR- $\beta$  (Claesson-Welsh *et al.*, *J. Biol. Chem.*, 264:1742-1747 (1989); Waltenberger *et al.*, 1994). Immunoprecipitates were bound to protein A-Sepharose, washed three times with RIPA buffer containing 1mM PMSF, 1mM sodium orthovanadate, washed twice with 10 mM Tris-HCl (pH 7.4),

and subjected to SDS-PAGE using a 7% gel. Polypeptides were transferred to nitrocellulose by Western blotting and analyzed using PY20 phosphotyrosine-specific monoclonal antibodies (Transduction Laboratories) or receptor-specific antiserum and the ECL detection method (Amersham Corp.).

5           The results of the experiment are presented in Figs. 14A and 14B. As shown in Fig. 14A, PAE cells expressing VEGFR-2 were stimulated with 10- or 2-fold concentrated medium from mock-transfected 293-EBNA cells (lanes 1 and 2), or with 2-, 5- or 10-fold concentrated medium from 293-EBNA cell cultures expressing the recombinant VEGF-C (lanes 3-6).  
10   VEGFR-2 was immunoprecipitated with specific antibodies and analyzed by SDS-PAGE and Western blotting using phosphotyrosine antibodies. For comparison, the stimulations were carried out with non-conditioned medium containing 50 ng/ml of purified recombinant VEGF (lanes 7 and 8). Lanes 6 and 7 show stimulation with VEGF-C- or VEGF- containing media pretreated with Flt4EC. As depicted in Fig. 14B, PDGFR- $\beta$ -expressing NIH 3T3 cells  
15   were stimulated with non-conditioned medium (lane 1), 5-fold concentrated CM from mock-transfected (lane 2) or VEGF-C - transfected (lanes 3 and 4) cells, or with non-conditioned medium containing 50 ng/ml of recombinant human PDGF-BB (lane 5). Medium containing VEGF-C was also pretreated  
20   with recombinant Flt4EC (lane 4). PDGFR- $\beta$  was immunoprecipitated with specific antibodies and analyzed by SDS-PAGE and Western blotting using phosphotyrosine antibodies with subsequent stripping and reprobing of the membrane with antibodies specific for PDGFR- $\beta$ .

Referring again to Fig. 14A, a basal level of tyrosine  
25   phosphorylation of VEGFR-2 was detected in cells stimulated by CM from the mock-transfected cells. A further concentration of this medium resulted in only a slight enhancement of VEGFR-2 phosphorylation (lanes 1 and 2). CM containing recombinant VEGF-C stimulated tyrosine autophosphorylation of VEGFR-2 and the intensity of the autophosphorylated polypeptide band was  
30   increased upon concentration of the VEGF-C CM (lanes 3-5). Furthermore, the stimulating effect was abolished after pretreatment of the medium with the Flt4EC affinity matrix (compare lanes 1, 5 and 6). The maximal effect of VEGF-C in this assay was comparable to the effect of recombinant VEGF added to unconditioned medium at concentration of 50 ng/ml (lane 8).  
35   Pretreatment of the medium containing VEGF with Flt4EC did not abolish its

stimulating effect on VEGFR-2 (compare lanes 7 and 8). These results suggest that the VEGF-C expression vector encodes a ligand not only for Flt4 (VEGFR-3), but also for VEGFR-2.

In order to further confirm that the stimulating effect of VEGF-C on tyrosine phosphorylation of VEGFR-3 and VEGFR-2 was receptor-specific, we analyzed the effect of VEGF-C on tyrosine phosphorylation of PDGF receptor  $\beta$  (PDGFR- $\beta$ ) which is abundantly expressed on fibroblastic cells. As can be seen from Fig. 14B, a weak tyrosine phosphorylation of PDGFR- $\beta$  was detected upon stimulation of Flt4-expressing NIH 3T3 cells with CM from the mock-transfected cells (compare lanes 1 and 2). A similar low level of PDGFR- $\beta$  phosphorylation was observed when the cells were incubated with CM from the VEGF-C transfected cells, with or without prior treatment with Flt4EC (lanes 3 and 4). In contrast, the addition of 50 ng/ml of PDGF-BB induced a prominent tyrosine autophosphorylation of PDGFR- $\beta$  (lane 5).

#### EXAMPLE 15

##### VEGF-C Stimulates Endothelial Cell Migration In Collagen Gel

CM from cell cultures transfected with the VEGF-C expression vector was placed in a well made in collagen gel and used to stimulate the migration of bovine capillary endothelial (BCE) cells in the three-dimensional collagen gel as follows.

BCE cells (Folkman *et al.*, *Proc. Natl. Acad. Sci. (USA)*, 76:5217-5221 (1979) were cultured as described in Pertovaara *et al.*, *J. Biol. Chem.*, 269:6271-74 (1994). The collagen gels were prepared by mixing type I collagen stock solution (5 mg/ml in 1 mM HCl) with an equal volume of 2x MEM and 2 volumes of MEM containing 10% newborn calf serum to give a final collagen concentration of 1.25 mg/ml. The tissue culture plates (5 cm diameter) were coated with about 1 mm thick layer of the solution, which was allowed to polymerize at 37°C. BCE cells were seeded on top of this layer. For the migration assays, the cells were allowed to attach inside a plastic ring (1 cm diameter) placed on top of the first collagen layer. After 30 min., the ring was removed and unattached cells were rinsed away. A second layer of collagen and a layer of growth medium (5% newborn calf serum (NCS)),

solidified by 0.75% low melting point agar (FMC BioProducts, Rockland, ME), were added. A well (3 mm diameter) was punched through all the layers on both sides of the cell spot at a distance of 4 mm, and the sample or control media were pipetted daily into the wells. Photomicrographs of the cells migrating out from the spot edge were taken after six days through an Olympus CK 2 inverted microscope equipped with phase-contrast optics. The migrating cells were counted after nuclear staining with the fluorescent dye bisbenzimidazole (1 mg/ml, Hoechst 33258, Sigma).

Fig. 15A depicts a comparison of the number of cells migrating at different distances from the original area of attachment towards wells containing media conditioned by the non-transfected (control) or transfected (mock; VEGF-C; VEGF) cells, 6 days after addition of the media. The number of cells migrating out from the original ring of attachment was counted in five adjacent 0.5 mm x 0.5 mm squares using a microscope ocular lens grid and 10x magnification. Cells migrating further than 0.5 mm were counted in a similar way by moving the grid in 0.5 mm steps. The experiments were carried out twice with similar results, and medium values from the one of the experiments are presented with standard error bars. The photographs in Fig. 15B depict phase-contrast microscopy and fluorescent microscopy of the nuclear staining of BCE cells migrating towards the wells containing media conditioned by the mock-transfected cells or by VEGF-C - transfected cells. The areas shown is approximately 1mm x 1.5mm, and arrows indicate the borders of the original ring of attachment.

After 6 days of treatment, the cultures were stained and cells at different distances outside of the original ring of attachment were counted using fluorescent nuclear staining and detection with a fluorescence microscope equipped with a grid. A comparison of the numbers of migrating cells in successive 0.5 mm x 0.5 mm areas is shown in Fig 15A. As can be seen from the columns, VEGF-C-containing CM stimulated cell migration more than medium conditioned by the non-transfected or mock-transfected cells but less than medium from cells transfected with a VEGF expression vector. An example of typical phase contrast and fluorescent microscopic fields of cultures stimulated with medium from mock-transfected or VEGF-C transfected cells is shown in Fig. 15B. Daily addition of 1 ng of FGF2 into the wells resulted in the migration of approximately twice the number of cells when compared to

the stimulation by CM from VEGF-transfected cells.

#### EXAMPLE 16

##### VEGF-C Is Expressed In Multiple Tissues

Northern blots containing 2 micrograms of isolated poly(A)<sup>+</sup> RNA from multiple human tissues (blot from Clontech Laboratories, Inc., Palo Alto, CA) were probed with radioactively labelled insert of the 2.1 kb VEGF-C cDNA clone. Northern blotting and hybridization analysis showed that the 2.4 kb RNA and smaller amounts of a 2.0 kb mRNA are expressed in multiple human tissues, most prominently in the heart, placenta, muscle, ovary and small intestine (Fig. 16A). Very little VEGF-C RNA was seen in the brain, liver or thymus and peripheral blood leukocytes (PBL) appeared negative. A similar analysis of RNA from human fetal tissues (Fig. 16B) shows that VEGF-C is highly expressed in the kidney and lung and to a lesser degree in the liver, while essentially no expression is detected in the brain. Interestingly, VEGF expression correlates with VEGF-C expression in these tissues, whereas VEGF-B is highly expressed in all tissues analyzed.

#### EXAMPLE 17

##### The VEGF-C Gene Localizes To Chromosome 4q34

A DNA panel of 24 interspecies somatic cell hybrids, which had retained one or two human chromosomes, was used for the chromosomal localization of the VEGF-C gene (Bios Laboratories, Inc., New Haven, CT). Primers were designed to amplify an about 250 bp fragment of the VEGF-C gene from somatic cell hybrid DNA. The primers and conditions for polymerase chain reaction (PCR) were 5'-TGAGTGATTGTAGCTGCTGTG-3' (forward) [SEQ ID NO: 34] and 5'-TATTGCAGCAACCCCCACATCT-3' (reverse) [SEQ ID NO: 35] for VEGF-C (94°C, 60s/62°C, 45s/72°C, 60s). The PCR products were evaluated by electrophoresis in 1% agarose gels and visualized by ethidium bromide staining in ultraviolet light. [ $\alpha$ -<sup>32</sup>P]-dCTP-labelled cDNA inserts of a plasmid representing the complete VEGF-C coding domain was used as a probe in Southern blotting and hybridization analysis of the somatic cell hybrid DNAs as instructed by the supplier (Bios Laboratories).

The cell lines for fluorescence *in situ* hybridization (FISH) were obtained from the American Type Culture Collection (Rockville, MD).

Purified DNA from P1 clones 7660 and 7661 (VEGF-C) (Genome Systems, Inc., St. Louis, MO) were confirmed positive by Southern blotting of *EcoRI*-digested DNA followed by hybridization with the VEGF-C cDNA. The P1 clones were then labelled by nick translation either with biotin-11-dUTP, biotin-14-ATP (Sigma Chemical Co., St. Louis, MO) or digoxigenin 11-dUTP (Boehringer Mannheim GmbH, Mannheim, Germany) according to standard protocols. PHA-stimulated peripheral blood lymphocyte cultures were treated with 5-bromodeoxyuridine (BrdU) at an early replicating phase to induce G-banding. See Takahashi *et al.*, *Human Genet.*, 86:14-16 (1995); Lemieux *et al.*, *Cytogenet. Cell Genet.*, 59:311-12 (1992). The FISH procedure was carried out in 50% formamide, 10% dextran sulphate in 2x SSC using well-known procedures. See *e.g.*, Rytkönnen *et al.*, *Cytogenet Cell Genet.*, 68:61-63 (1995); Lichter *et al.*, *Proc. Natl. Acad. Sci. (USA)*, 85:9664-68 (1988). Repetitive sequences were suppressed with 50-fold excess of Cot-1 DNA (BRL, Gaithersburg, MD) compared with the labeled probe. Specific hybridization signals were detected by incubating the hybridized slides in labelled antidigoxigenin antibodies, followed by counterstaining with 0.1mmol/L 4,6-diamino-2-phenylindole. Probe detection for two-color experiments was accomplished by incubating the slides in fluorescein isothiocyanate (FITC)-anti-digoxigenin antibodies (Sigma Chemical Co.) and Texas red-avidin (Vector Laboratories, Burlingame, CA) or rhodamine-anti-digoxigenin and FITC-avidin.

Multi-color digital image analysis was used for acquisition, display and quantification of hybridization signals of metaphase chromosomes. The system contains a PXL camera (Photometrics Inc., Tucson, AZ) attached to a PowerMac 7100/Av workstation. IPLab software controls the camera operation, image acquisition and Ludl Filter wheel. At least 50 nuclei were scored. Overlapping nuclei and clusters of cells were ignored. A slide containing normal lymphocyte metaphase spreads and interphase nuclei was included in each experiment to control for the efficiency and specificity of the hybridization.

In order to determine the chromosomal localization of the human VEGF-C gene, DNAs from human rodent somatic cell hybrids containing defined sets of human chromosomes were analyzed by Southern blotting and hybridization with the VEGF-C cDNA probe. Among 24 DNA

samples on the hybrid panel, representing different human chromosomes, human-specific signals were observed only in hybrids which contained human chromosome 4. The results were confirmed by PCR of somatic cell hybrid DNA using VEGF-C specific primers, where amplified bands were obtained only from DNAs containing human chromosome 4.

A genomic P1 plasmid for VEGF-C was isolated using specific primers and PCR and verified by Southern blotting and hybridization using a VEGF-B specific cDNA probe. The chromosomal localization of VEGF-C was further studied using metaphase FISH. Using the P1 probe for VEGF-C in FISH a specific hybridization to the 4q34 chromosomal band was detected in 40 out of 44 metaphases (Fig. 17). Double-fluorochrome hybridization using a cosmid probe specific for the aspartylglucosaminidase (AGA) gene showed that VEGF-C is located just proximal to the AGA gene previously mapped to the 4q34-35 chromosomal band.

Biotin labelled VEGF-C P1 and digoxigenin labeled AGA cosmid probes were hybridized simultaneously to metaphase chromosomes. This experiment demonstrated that the AGA gene is more telomerically located than the VEGF-C gene. The foregoing example demonstrates the utility of polynucleotides of the invention as chromosomal markers.

#### EXAMPLE 18

##### Effect of glucose concentration and hypoxia on VEGF, VEGF-B and VEGF-C mRNA levels in C6 glioblastoma cells

Confluent cultures of C6 cells (ATCC CCL 107) were grown on 10 cm diameter tissue culture plates containing 2.5 ml of DMEM and 5% fetal calf serum plus antibiotics. The cultures were exposed for 16 hours to normoxia in a normal cell culture incubator containing 5% CO<sub>2</sub> (Fig. 18: lanes marked -) or hypoxia (Fig. 18: lanes marked +) by closing the culture plates in an airtight glass chamber and burning a piece of wood inside until the flame was extinguished due to lack of oxygen. Polyadenylated RNA was isolated (as in the other examples), and 8 micrograms of the RNA was electrophoresed and blot-hybridized with a mixture of the VEGF, VEGF-B and VEGF-C probes (see Fig. 12). The results show that hypoxia strongly induces VEGF (VEGF-A) mRNA expression (compare lanes - and +), both in low

and high glucose, but has no significant effect on the VEGF-B mRNA levels. The VEGF-C mRNA isolated from hypoxic cells runs slightly faster in gel electrophoresis and an extra band of faster mobility can be seen below the upper mRNA band. This observation suggests that hypoxia affects VEGF-C RNA processing. One explanation for this observation is that VEGF-C mRNA splicing is altered, affecting the VEGF-C open reading frame and resulting in an alternative VEGF-C protein being produced by hypoxic cells. Such alternative forms of VEGF-C and VEGF-C-encoding polynucleotides are contemplated as an aspect of the invention. This data indicates screening and diagnostic utilities for polynucleotides and polypeptides of the invention, such as methods whereby a biological sample is screened for the hypoxia-induced form of VEGF-C and/or VEGF-C mRNA. The data further suggests a therapeutic indication for antibodies and/or other inhibitors of the hypoxia-induced form of VEGF-C or the normal form of VEGF-C.

#### EXAMPLE 19

**Pulse-chase labeling and immunoprecipitation  
of VEGF-C polypeptides from 293 cells  
transfected with VEGF-C expression vector.**

The following VEGF-C branched amino-terminal peptide, designated PAM126, was synthesized for production of anti-VEGF-C antiserum:

NH<sub>2</sub>-E-E-T-I-K-F-A-A-A-H-Y-N-T-E-I-L-K-COOH (SEQ ID NO: 39).

In particular, PAM126 was synthesized as a branched polylysine structure K3PA4 having four peptide acid (PA) chains attached to two available lysine (K) residues. The synthesis was performed on a 433A Peptide Synthesizer (Applied Biosystems) using Fmoc-chemistry and TentaGel S MAP RAM10 resin mix (RAPP Polymere GmbH, Tübingen, Germany), yielding both cleavable and resin-bound peptides. The cleavable peptide was purified via reverse phase HPLC and was used together with the resin-bound peptide in immunizations. The correctness of the synthesis products were confirmed using mass-spectroscopy (Lasermatt).

The peptide was dissolved in phosphate buffered saline (PBS), mixed with Freund's adjuvant, and used for immunization of rabbits at bi-weekly intervals using methods standard in the art (Harlow and Lane,

*Antibodies, a laboratory manual*, Cold Spring Harbor Laboratory Press (1988)). Antisera obtained after the fourth booster immunization was used for immunoprecipitation of VEGF-C in pulse-chase experiments, as described below.

5 For pulse-chase analysis, 293 cells transfected with a VEGF-C expression vector (i.e., the FLT4-L cDNA inserted into the pREP7 expression vector as described above) were incubated for 30 minutes in methionine-free, cysteine-free, serum-free DMEM culture medium at 37°C. The medium was then changed, and 200 µCi of <sup>35</sup>S-methionine and <sup>35</sup>S-cysteine (Promix,  
10 Amersham, Buckinghamshire, England) was added. The cell layers were incubated in this labeling medium for two hours, washed with PBS, and incubated for 0, 15, 30, 60, 90, 120, or 180 minutes in serum-free DMEM (chase). After the various chase periods, the medium was collected, the cells were again washed two times in PBS, and lysed in immunoprecipitation buffer.  
15 The VEGF-C polypeptides were analyzed from both the culture medium and from the cell lysates by immunoprecipitation, using the VEGF-C-specific antiserum raised against the NH<sub>2</sub>-terminal peptide (PAM126) of the 23 kD VEGF-C form. Immunoprecipitated polypeptides were analyzed via SDS-PAGE followed by autoradiography.

20 Referring to Fig. 19, the resultant autoradiograms demonstrate that immediately after a 2 hour labeling (chase time 0), the VEGF-C vector-transfected cells contained a radioactive 55 kD polypeptide band, which is not seen in mock-transfected cells (M). This 55 kD polypeptide band gradually diminishes in intensity with increasing chase periods, and is no longer detected  
25 in the cells by 180 minutes of chase. A 32 kD polypeptide band also is observed in VEGF-C transfected cells (and not mock-transfected cells). This 32 kD band disappears with similar kinetics to that of the 55 kD band. Simultaneously, increasing amounts of 32 kD (arrow) and subsequently 23 kD (arrow) and 14 kD polypeptides appear in the medium.

30 Collectively, the data from the pulse-chase experiments indicate that the 55 kD intracellular polypeptide represents a pro-VEGF-C polypeptide, which is not secreted from cells, but rather is first proteolytically cleaved into the 32 kD form. The 32 kD form is secreted and simultaneously further processed by proteolysis into the 23 kD and 14 kD forms. Without intending  
35 to be limited to a particular theory, it is believed that processing of the VEGF-

C precursor occurs as removal of a signal sequence, removal of the COOH-terminal domain (BR3P), and removal of an amino terminal peptide, resulting in a VEGF-C polypeptide having the TEE... amino terminus.

At high resolution, the 23 kD polypeptide band appears as a closely spaced polypeptide doublet, suggesting heterogeneity in cleavage or glycosylation.

#### EXAMPLE 20

##### Isolation of Mouse cDNA Clones Encoding VEGF-C

To clone a mouse variant of VEGF-C, approximately  $1 \times 10^6$  bacteriophage lambda clones of a commercially-available 12 day mouse embryonal cDNA library (lambda EXlox library, Novagen, catalog number 69632-1) were screened with a radiolabeled fragment of human VEGF-C cDNA containing nucleotides 495 to 1661 of SEQ ID NO: 32. One positive clone was isolated.

A 1323 bp *EcoRI*/*HindIII* fragment of the insert of the isolated mouse cDNA clone was subcloned into the corresponding sites of the pBluescript SK+ vector (Stratagene) and sequenced. The cDNA sequence of this clone was homologous to the human VEGF-C sequence reported herein, except that about 710 bp of 5'-end sequence present in the human clone was not present in the mouse clone.

For further screening of mouse cDNA libraries, a *HindIII*-*BstXI* (*HindIII* site is from the pBluescript SK+ polylinker) fragment of 881 bp from the coding region of the mouse cDNA clone was radiolabeled and used as a probe to screen two additional mouse cDNA libraries. Two additional cDNA clones from an adult mouse heart ZAP II cDNA library (Stratagene, catalog number 936306) were identified. Three additional clones also were isolated from a mouse heart 5'-stretch-plus cDNA library in  $\lambda$ gt11 (Clontech Laboratories, Inc., catalog number ML5002b). Of the latter three clones, one was found to contain an insert of about 1.9 kb. The insert of this cDNA clone was subcloned into *EcoRI* sites of pBluescript SK+ vector and both strands of this clone were completely sequenced, resulting in the nucleotide and deduced amino acid sequences shown in SEQ ID NOs: 40 and 41.

It is contemplated that the polypeptide corresponding to SEQ ID NO: 41 is processed into a mature mouse VEGF-C protein, in a manner

analogous to the processing of the human VEGF-C prepropeptide. Putative cleavage sites for the mouse protein are identified using procedures outlined above for identification of cleavage sites for the human VEGF-C polypeptide.

The foregoing example demonstrates the utility of polynucleotides of the invention for identifying and isolating polynucleotides encoding other non-human mammalian variants of VEGF-C. Such identified and isolated polynucleotides, in turn, can be expressed (using procedures similar to those described in preceding examples) to produce recombinant polypeptides corresponding to non-human mammalian variants of VEGF-C.

#### EXAMPLE 21

##### N-terminal peptide sequence analyses of recombinant VEGF-C

Cells (293 EBNA) transfected with VEGF-C cDNA (see Example 13) secrete several forms of recombinant VEGF-C (Fig. 21A, lane IP). In the absence of alkylation, the three major, proteolytically-processed forms of VEGF-C migrate in SDS-PAGE as proteins with apparent molecular masses of 32/29 kD (doublet), 21 kD and 15 kD. Two minor polypeptides exhibit approximate molecular masses of 63 and 52 kD, respectively. One of these polypeptides is presumably a glycosylated and non-processed form; the other polypeptide is presumably glycosylated and partially processed.

To determine sites of proteolytic cleavage of the VEGF-C precursor, an immunoaffinity column was used to purify VEGF-C polypeptides from the conditioned medium of 293 EBNA cells transfected with VEGF-C cDNA. To prepare the immunoaffinity column, a rabbit was immunized with a synthetic peptide corresponding to the amino-terminus of mature VEGF-C secreted from the PC-3 cell line (amino acids 104-120 in SEQ ID NO: 33: H<sub>2</sub>N-EETIKFAAAHYNTEILK; see PAM126 in Example 19). The IgG fraction was isolated from the serum of the immunized rabbit using protein A Sepharose (Pharmacia). The isolated IgG fraction was covalently bound to CNBr-activated Sepharose CL-4B (Pharmacia) using standard techniques at a concentration of 5 mg IgG/ml of Sepharose. This immunoaffinity matrix was used to isolate processed VEGF-C from 1.2 liters of the conditioned medium (CM).

The purified material eluted from the column was analyzed by gel electrophoresis and Western blotting. Fractions containing VEGF-C

polypeptides were combined, dialyzed against 10 mM Tris HCl, vacuum-dried, electrotransferred to Immobilon-P (polyvinylidene difluoride or PVDF) transfer membrane (Millipore, Marlborough, MA) and subjected to N-terminal amino acid sequence analysis.

5           The polypeptide band of 32 kD yielded two distinct sequences: NH<sub>2</sub>-FESGLDLSDA... and NH<sub>2</sub>-AVVMTQTPAS... (SEQ ID NO: 51), the former corresponding to the N-terminal part of VEGF-C after cleavage of the signal peptide, starting from amino acid 32 (SEQ ID NO: 33), and the latter corresponding to the kappa-chain of IgG, which was present in the purified  
10       material due to "leakage" of the affinity matrix during the elution procedure.

          In order to obtain the N-terminal peptide sequence of the 29 kD form of VEGF-C, a construct (VEGF-C NHis) encoding a VEGF-C variant was generated. In particular, the construct encoded a VEGF-C variant that fused a 6xHis tag to the N-terminus of the secreted precursor (*i.e.*, between  
15       amino acids 31 and 33 in SEQ ID NO: 33). The phenylalanine at position 32 was removed to prevent possible cleavage of the tag sequence during secretion of VEGF-C. The VEGF-C NHis construct was cloned into pREP7 as a vector; the construction is described more fully in Example 28, below.

          The calcium phosphate co-precipitation technique was used to  
20       transfect VEGF-C NHis into 293 EBNA cells. Cells were incubated in DMEM/10% fetal calf serum in 15 cm cell culture dishes (a total of 25 plates). The following day, the cells were reseeded into fresh culture dishes (75 plates) containing the same medium and incubated for 48 hours. Cell layers were then washed once with PBS and DMEM medium lacking FCS was  
25       added. Cells were incubated in this medium for 48 hours and the medium was collected, cleared by centrifugation at 5000 x g and concentrated 500X using an Ultrasette Tangential Flow Device (Filtron, Northborough, MA), as described in Example 5 above. VEGF-C NHis was purified from the concentrated conditioned medium using TALON™ Metal Affinity Resin  
30       (Clontech Laboratories, Inc.) and the manufacturer's protocol for native protein purification using imidazole-containing buffers. The protein was eluted with a solution containing 20 mM Tris-HCl (pH 8.0), 100 mM NaCl, and 200 mM imidazole. The eluted fractions containing purified VEGF-C NHis were detected by immunoblotting with Antiserum 882 (antiserum from rabbit 882).  
35       Fractions containing VEGF-C NHis were combined, dialyzed and vacuum-

dried. As can be seen in Fig. 27, due to the presence of the 6xHis tag at the N-terminus of this form of VEGF-C, the upper component of the major doublet of the VEGF-CNH<sub>2</sub> migrates slightly slower than the 32 kD form of wild type VEGF-C, thereby improving the separation of the VEGF-CNH<sub>2</sub> 32 kD variant from the 29 kD band using SDS-PAGE. Approximately 15 µg of the purified VEGF-C were subjected to SDS-PAGE under reducing conditions, electrotransferred to Immobilon-P (PVDF) transfer membrane (Millipore, Inc., Marlborough, MA) and the band at 29 kD was subjected to N-terminal amino acid sequence analysis. This sequence analysis revealed an N-terminal sequence of H<sub>2</sub>N-SLPAT . . . , corresponding to amino acids 228-232 of VEGF-C (SEQ ID NO: 33).

The polypeptide band of 21 kD yielded the sequence H<sub>2</sub>N-AHYNTEILKS . . . , corresponding to an amino-terminus starting at amino acid 112 of SEQ ID NO: 33. Thus, the proteolytic processing site which results in the 21 kD form of VEGF-C produced by transfected 293 EBNA cells apparently occurs nine amino acid residues downstream of the cleavage site which results in the 23 kD form of VEGF-C secreted by PC-3 cells.

The N-terminus of the 15 kD form was identical to the N-terminus of the 32 kD form (NH<sub>2</sub>-FESGLDLSDA...). The 15 kD form was not detected when recombinant VEGF-C was produced by COS cells. This suggests that production of this form is cell lineage specific.

#### Example 22

##### Dimeric and monomeric forms of VEGF-C

The composition of VEGF-C dimers was analyzed as follows.

Cells (293 EBNA cells), transfected with the pREP7 VEGF-C vector as described in Example 11, were metabolically labelled with Pro-mix L-[<sup>35</sup>S] labelling mix (Amersham Corp.) to a final concentration of 100 µCi/ml.

In parallel, a VEGF-C mutant, designated "R102S", was prepared and analyzed. To prepare the DNA encoding VEGF-C-R102S, the arginine codon at position 102 of SEQ ID NO: 33 was replaced with a serine codon. This VEGF-C-R102S-encoding DNA, in a pREP7 vector, was transfected into 293 EBNA cells and expressed as described above. VEGF-C polypeptides were immunoprecipitated using antisera 882 (obtained by immunization of a rabbit with a polypeptide corresponding to residues 104-120

of SEQ ID NO: 33 (see previous Example)) and antisera 905 (obtained by immunization of a rabbit with a polypeptide corresponding to a portion of the prepro- VEGF-C leader: H<sub>2</sub>N-ESGLDLSDAEPDAGEATAYASK (residues 33 to 54 of SEQ ID NO: 33).

5           The immunoprecipitates from each cell culture were subjected to SDS-PAGE under non-denaturing conditions (Fig. 21B). Bands 1-6 were cut out from the gel, soaked for 30 minutes in 1x gel-loading buffer containing 200 mM  $\beta$ -mercaptoethanol, and individually subjected to SDS-PAGE under denaturing conditions (Figs. 21A and 21C, lanes 1-6).

10           As can be seen from Figures 21A-C, each high molecular weight form of VEGF-C (Fig. 21B, bands 1-4) consists of at least two monomers bound by disulfide bonds (Compare Figs. 21A and 21C, lanes 1-4, in the reducing gels). The main component of bands 1-3 is the doublet of 32/29 kD, where both proteins are present in an equimolar ratio. The main  
15           fraction of the 21 kD form is secreted as either a monomer or as a homodimer connected by means other than disulfide bonds (bands 6 and lanes 6 in Figs. 21A-C).

          The R102S mutation creates an additional site for N-linked glycosylation in VEGF-C at the asparagine residue at position 100 in SEQ ID  
20           NO: 33. Glycosylation at this additional glycosylation site increases the apparent molecular weight of peptides containing the site, as confirmed in Figures 21A-C and Figures 22A-B. The additional glycosylation lowers the mobility of forms of VEGF-C-R102S that contain the additional glycosylation site, when compared to peptides of similar primary structure corresponding to  
25           VEGF-C. Figures 21A-C and Figures 22A-B reveal that the VEGF-C-R102S polypeptides corresponding to the 32 kD and 15 kD forms of wt VEGF-C exhibit increased apparent molecular weights, indicating that each of these peptides contains the newly introduced glycosylation site. In particular, the VEGF-C-R102S peptide corresponding to the 15 kD peptide from VEGF-C  
30           comigrates on a gel with the 21 kD form of the wild type (wt) VEGF-C, reflecting a shift on the gel to a position corresponding to a greater apparent molecular weight. (Compare lanes 4 in Figures 21A and 21C).

          In a related experiment, another VEGF-C mutant, designated "R226,227S," was prepared and analyzed. To prepare a DNA encoding  
35           VEGF-C-R226,227S, the arginine codons at positions 226 and 227 of SEQ ID

NO: 33 were replaced with serine codons by site-directed mutagenesis. The resultant DNA was transfected into 293 EBNA cells as described above and expressed and analyzed under the same conditions as described for VEGF-C and VEGF-C-R102S. In the conditioned medium from the cells expressing VEGF-C-R226,227S, no 32 kD form of VEGF-C was detected. These results indicate that a C-terminal cleavage site of wild-type VEGF-C is adjacent to residues 226 and 227 of SEQ ID NO: 33, and is destroyed by the mutation of the arginines to serines. Again, the mobility of the 29 kD component of the doublet was unchanged (Figures 22A-B).

Taken together, these data indicate that the major form of the processed VEGF-C is a heterodimer consisting of (1) a polypeptide of 32 kD containing amino acids 32-227 of the prepro-VEGF-C (amino acids 32 to 227 in SEQ ID NO: 33) attached by disulfide bonds to (2) a polypeptide of 29 kD beginning with amino acid 228 in SEQ ID NO: 33. These data are also supported by a comparison of the pattern of immunoprecipitated, labelled VEGF-C forms using antisera 882 and antisera 905.

When VEGF-C immunoprecipitation was carried out using conditioned medium, both antisera (882 and 905) recognized some or all of the three major processed forms of VEGF-C (32/29 kD, 21 kD and 15 kD).

When the conditioned medium was reduced by incubation in the presence of 10 mM dithiothreitol for two hours at room temperature with subsequent alkylation by additional incubation with 25 mM iodoacetamide for 20 minutes at room temperature, neither antibody precipitated the 29 kD component, although antibody 882 still recognized polypeptides of 32 kD, 21 kD and 15 kD. These results are consistent with the nature of the peptide antigen used to elicit the antibodies contained in antisera 882, a peptide containing amino acids 2-18 of SEQ ID NO: 33. On the other hand, antisera 905 recognized only the 32 kD and 15 kD polypeptides, which include sequence of the peptide (amino acids 33 to 54 of SEQ ID NO: 33) used for immunization to obtain antisera 905. Taking into account the mobility shift of the 32 kD and 15 kD forms, the immunoprecipitation results with the R102S mutant were similar (Figs. 23A-B). The specificity of antibody 905 is confirmed by the fact that it did not recognize a VEGF-C  $\Delta$ N variant form wherein the N-terminal propeptide spanning residues 32-102 of the unprocessed polypeptide had been deleted (Fig. 23B).

The results of these experiments also demonstrate that the 21 kD polypeptide is found (1) in heterodimers with other molecular forms (see Figs. 21A-C and Figs. 22A-B), and (2) secreted as a monomer or a homodimer held by bonds other than disulfide bonds (Figs. 21A and 21B, lanes 6).

5           The experiments disclosed in this example demonstrate that several forms of VEGF-C exist. A variety of VEGF-C monomers were observed and these monomers can vary depending on the level and pattern of glycosylation. In addition, VEGF-C was observed as a multimer, for example a homodimer or a heterodimer. The processing of VEGF-C is schematically  
10       presented in Fig. 37 (disulfide bonds not shown). All forms of VEGF-C are within the scope of the present invention.

#### Example 23

##### *In situ* Hybridization of Mouse Embryos

To analyze VEGF-C mRNA distribution in different cells and  
15       tissues, sections of 12.5 and 14.5-day post-coitus (p.c.) mouse embryos were prepared and analyzed via *in situ* hybridization using labeled VEGF-C probes. *In situ* hybridization of tissue sections was performed as described Västrik *et al.*, *J. Cell Biol.*, 128:1197-1208 (1995). A mouse VEGF-C antisense RNA probe was generated from linearized pBluescript II SK+ plasmid (Stratagene  
20       Inc., La Jolla, CA), containing a cDNA fragment corresponding to nucleotides 499-979 of a mouse VEGF-C cDNA (SEQ ID NO: 40). This clone was obtained from a partial clone isolated from the Novagen library (see the 1322 bp cDNA clone of Fig. 31A), from which the 3' noncoding region and the BR3P repeats had been removed by exonuclease III treatment. Radiolabeled  
25       RNA was synthesized using T7 polymerase and [<sup>35</sup>S]-UTP (Amersham). Mouse VEGF-B antisense and sense RNA probes were synthesized in a similar manner from linearized pCRII plasmid containing the mouse VEGF-B cDNA insert as described Olofsson *et al.*, *Proc. Natl. Acad. Sci. (USA)*, 93:2576-2581 (1996). The high stringency wash was for 45 minutes at 65°C in a  
30       solution containing 30 mM DTT and 4 x SSC. The slides were exposed for 28 days, developed and stained with hematoxylin. For comparison, similar sections were hybridized with a VEGFR-3 probe and the 12.5-day p.c. embryos were also probed for VEGF-B mRNA.

Figures 34A-D show darkfield (Figures 34A-C) and lightfield

(Figure 34D) photomicrographs of 12.5 day p.c. embryo sections probed with the antisense (Fig. 34A) and sense (Figs. 34C-D) VEGF-C probes. Fig. 34A illustrates a parasagittal section, where VEGF-C mRNA is particularly prominent in the mesenchyme around the vessels surrounding the developing metanephros (mn). In addition, hybridization signals were observed between the developing vertebrae (vc), in the developing lung mesenchyme (lu), in the neck region and developing forehead. The specificity of these signals is evident from the comparison with VEGF-B expression in an adjacent section (Fig. 34B), where the myocardium gives a very strong signal and lower levels of VEGF-B mRNA are detected in several other tissues. Both genes appear to be expressed in between the developing vertebrae (vc), in the developing lung (lu) and forehead. Hybridization of the VEGF-C sense probe showed no specific expression within these structures (Fig. 34C).

Figs. 35A-D show a comparison of the expression patterns of VEGF-C and VEGFR-3 in 12.5 day p.c. mouse embryos in the jugular region, where the developing dorsal aorta and cardinal vein are located. This is the area where the first lymphatic vessels sprout from venous sac-like structures according to a long-standing theory. Sabin, *Am. J. Anat.*, 9:43-91 (1909). As can be seen from Figs. 35A-D, an intense VEGF-C signal is detected in the mesenchyme surrounding the developing venous sacs (Figs. 35A and 35C) which are positive for VEGFR-3 (Figs. 35B and 35D).

The mesenterium supplies the developing gut with blood and contains developing lymphatic vessels. The developing 14.5 day p.c. mesenterium is positive for VEGF-C mRNA, with particularly high expression in connective tissue surrounding certain vessels (arrowheads in Figs. 35A-H). This signal in Fig. 35E should be distinguished from the false positive reflection of light from red blood cells within the vessel, shown with an asterisk. The adjacent mesenterial VEGFR-3 signals shown in Fig. 35F originate from small capillaries of the mesenterium (arrowheads). Therefore, there appears to be a paracrine relationship between the production of the mRNAs for the two growth factors. This data indicates that VEGF-C is expressed in a variety of tissues. Moreover, the pattern of expression is consistent with a role for VEGF-C in venous and lymphatic vessel development. Further, the data reveals that VEGF-C is expressed in non-human animals.

Example 24

Analysis of VEGF, VEGF-B, and VEGF-C mRNA Expression  
in Fetal and Adult Tissues

A human fetal tissue Northern blot containing 2  $\mu$ g of  
5 polyadenylated RNAs from brain, lung, liver and kidney (Clontech Inc.) was  
hybridized with a pool of the following probes: a human full-length VEGF-C  
cDNA insert (Genbank Acc. No. X94216), a human VEGF-B<sub>167</sub> cDNA  
fragment (nucleotides 1-382, Genbank Acc. No. U48800) obtained by PCR  
amplification; and a human VEGF 581 bp cDNA fragment covering base pairs  
10 57-638 (Genbank Acc. No. X15997). Blots were washed under stringent  
conditions, using techniques standard in the art.

Mouse embryo multiple tissue Northern blot (Clontech Inc.)  
containing 2  $\mu$ g of polyadenylated RNAs from 7, 11, 15 and 17 day postcoital  
(p.c.) embryos was hybridized with mouse VEGF-C cDNA fragment (base  
15 pairs 499-656). A mouse adult tissue Northern blot was hybridized with the  
probes for human VEGF, VEGF-B<sub>167</sub>, VEGF-C and with a VEGFR-3 cDNA  
fragment (nucleotides 1-595; Genbank Acc. No. X68203).

In adult mouse tissues, both 2.4 kb and 2.0 kb mRNA signals  
were observed with the VEGF-C probe, at an approximately 4:1 ratio. The  
20 most conspicuous signals were obtained from lung and heart RNA, while  
kidney, liver, brain, and skeletal muscle had lower levels, and spleen and  
testis had barely visible levels (Figure 33A). As in the human tissues, VEGF  
mRNA expression in adult mice was most abundant in lung and heart RNA,  
whereas the other samples showed less coordinate regulation with VEGF-C  
25 expression. Skeletal muscle and heart tissues gave the highest VEGF-B  
mRNA levels from adult mice, as previously reported Olofsson *et al.*, *Proc.*  
*Natl. Acad. Sci. (USA)*, 93:2576-2581 (1996). Comparison with VEGFR-3  
expression showed that the tissues where VEGF-C is expressed also contain  
mRNA for its cognate receptor tyrosine kinase, although in the adult liver  
30 VEGFR-3 mRNA was disproportionately abundant.

To provide a better insight into the regulation of the VEGF-C  
mRNA during embryonic development, polyadenylated RNA isolated from  
mouse embryos of various gestational ages (7-17 day p.c.) was hybridized with  
the mouse VEGF-C probe. These analyses showed that the amount of 2.4 kb  
35 VEGF-C mRNA is relatively constant throughout the gestational period

(Figure 33B).

#### Example 25

##### Regulation of mRNAs for VEGF family members by serum, interleukin-1 and dexamethasone in human fibroblasts in culture

- 5 Human IMR-90 fibroblasts were grown in DMEM medium containing 10% FCS and antibiotics. The cells were grown to 80% confluence, then starved for 48 hours in 0.5 % FCS in DMEM. Thereafter, the growth medium was changed to DMEM containing 5 % FCS, with or without 10ng/ml Interleukin-1 (IL-1) and with or without 1mM
- 10 dexamethasone, as indicated in Figs. 25A-B. The culture plates were incubated with these additions for the times indicated, and total cellular RNA was isolated using the TRIZOL kit (GIBCO-BRL). About 20  $\mu$ g of total RNA from each sample was electrophoresed in 1.5% formaldehyde-agarose gels as described in Sambrook *et al.*, *supra* (1989). The gel was used for Northern
- 15 blotting and hybridization with radiolabeled insert DNA from the human VEGF (VEGF-A) clone (a 581 bp cDNA covering bps 57-638, Genbank Acc. No. 15997) and a human VEGF-B<sub>167</sub> cDNA fragment (nucleotides 1-382, Genbank Acc. No. U48800) (Fig. 25B). Subsequently, the Northern blots were probed with radiolabelled insert from the VEGF-C cDNA plasmid (Fig.
- 20 25A). Primers were labelled using a standard technique involving enzymatic extension reactions of random primers, as would be understood by one of ordinary skill in the art. The mobilities of the 28S and 18S ribosomal RNA bands are indicated, based on UV photography of ethidium bromide stained RNA before the transfer.
- 25 As can be seen in Figs. 25A-B, very low levels of VEGF-C and VEGF-A are expressed by the starved IMR-90 cells as well as cells after 1 hour of stimulation. In contrast, abundant VEGF-B mRNA signal is visible under these conditions. After a 4 hours of serum stimulation, there is a strong induction of VEGF-C and VEGF mRNAs, which are further increased in the
- 30 IL-1 treated sample. The effect of IL-1 seems to be abolished in the presence of dexamethasone. A similar pattern of enhancement is maintained in the 8 hour sample, but a gradual down-regulation of all signals occurs for both RNAs in the 24 hour and 48 hour samples. In contrast, VEGF-B mRNA levels remain constant and thus show remarkable stability throughout the time

period. The results are useful in guiding efforts to use VEGF-C in methods for treating a variety of disorders.

#### Example 26.

##### Expression and Analysis of Recombinant VEGF-C

5           The mouse VEGF-C cDNA was expressed as a recombinant protein and the secreted protein was analyzed for its receptor binding properties. The binding of mouse VEGF-C to the human VEGFR-3 extracellular domain was studied by using media from Bosc23 cells transfected with mouse VEGF-C cDNA in a retroviral expression vector.

10           The 1.8 kb mouse VEGF-C cDNA was cloned as an *EcoRI* fragment into the retroviral expression vector pBabe-puro containing the SV40 early promoter region Morgenstern *et al.*, *Nucl. Acids Res.*, 18:3587-3595 (1990), and transfected into the Bosc23 packaging cell line by the calcium-phosphate precipitation method Pearet *et al.*, *Proc. Natl. Acad. Sci. (USA)*,  
15   90:8392-8396 (1994). For comparison, Bosc23 cells also were transfected with the previously- described human VEGF-C construct in the pREP7 expression vector. The transfected cells were cultured for 48 hours prior to metabolic labelling. Cells were changed into DMEM medium devoid of cysteine and methionine, and, after 45 minutes of preincubation and medium  
20   change, Pro-mix™ L-[<sup>35</sup>S] *in vitro* cell labelling mix (Amersham Corp.), in the same medium, was added to a final concentration of about 120  $\mu$ Ci/ml. After 6 hours of incubation, the culture medium was collected and clarified by centrifugation.

          For immunoprecipitation, 1 ml aliquots of the media from  
25   metabolically-labelled Bosc23 cells transfected with empty vector or mouse or human recombinant VEGF-C, respectively, were incubated overnight on ice with 2  $\mu$ l of rabbit polyclonal antiserum raised against an N-terminal 17 amino acid peptide of mature human VEGF-C (H<sub>2</sub>N-EETIKFAAAHYNTEILK) (SEQ ID NO: 33, residues 104-120). Thereafter, the samples were incubated with  
30   protein A sepharose for 40 minutes at 4°C with gentle agitation. The sepharose beads were then washed twice with immunoprecipitation buffer and four times with 20 mM Tris-HCl, pH 7.4. Samples were boiled in Laemmli buffer and analyzed by 12.5% sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE).

Immunoprecipitation of VEGF-C from media of transfected and metabolically-labelled cells revealed bands of approximately  $30\text{-}32 \times 10^3 \text{ M}_r$  (a doublet) and  $22\text{-}23 \times 10^3 \text{ M}_r$  in 12.5% SDS-PAGE. These bands were not detected in samples from nontransfected or mock-transfected cells as shown in Fig. 32A (*i.e.*, lanes marked "vector"). These results show that antibodies raised against human VEGF-C recognize the corresponding mouse ligand.

For receptor binding experiments, 1 ml aliquots of media from metabolically-labelled Bosc23 cells were incubated with VEGFR-3 extracellular domain covalently coupled to sepharose for 4 hours at  $4^\circ\text{C}$  with gentle mixing. The VEGFR-3 extracellular domain is described in co-owned, co-pending U.S. Patent Application Serial Number 08/340,011, incorporated herein by reference. The sepharose beads were washed four times with ice-cold phosphate buffered saline (PBS), and the samples were analyzed by gel electrophoresis as described in Joukov *et al.*, *EMBO J.*, 15:290-298 (1996).

As can be seen from Fig. 32A, similar  $30\text{-}32 \times 10^3 \text{ M}_r$  doublet and  $22\text{-}23 \times 10^3 \text{ M}_r$  polypeptide bands were obtained in the receptor binding assay as compared to the immunoprecipitation assay. Thus, mouse VEGF-C binds to human VEGFR-3. The slightly faster mobility of the mouse VEGF-C polypeptides may be caused by the four amino acid residue difference observed in sequence analysis (residues H88-E91, Fig. 32B).

The capacity of mouse recombinant VEGF-C to induce VEGFR-3 autophosphorylation was also investigated. For the VEGFR-3 receptor stimulation experiments, subconfluent NIH 3T3-VEGFR-3 cells, Pajusola *et al.*, *Oncogene*, 9:3545-3555 (1994), were starved overnight in serum-free medium containing 0.2% BSA. In general, the cells were stimulated with the conditioned medium from VEGF-C vector-transfected cells for 5 minutes, washed three times with cold PBS containing  $200 \mu\text{M}$  vanadate, and lysed in RIPA buffer for immunoprecipitation analysis. The lysates were centrifuged for 25 minutes at  $16000 \times g$  and the resulting supernatants were incubated for 2 hours on ice with the specific antisera, followed by immunoprecipitation using protein A-sepharose and analysis in 7% SDS-PAGE. Polypeptides were transferred to nitrocellulose and analyzed by immunoblotting using anti-phosphotyrosine (Transduction Laboratories) and anti-receptor antibodies, as described by Pajusola *et al.*, *Oncogene*, 9:3545-3555 (1994). Filter stripping was carried out at  $50^\circ\text{C}$  for 30 minutes in 100 mM 2-mercaptoethanol, 2%

SDS, 62.5 mM Tris-HCl, pH 6.7, with occasional agitation. U.S. Patent Application Serial Number 08/340,011. The results of the experiment are shown in Fig. 32B. The results demonstrate that culture medium containing mouse VEGF-C stimulates the autophosphorylation of VEGFR-3 to a similar extent as human baculoviral VEGF-C or the tyrosyl phosphatase inhibitor pervanadate.

VEGFR-2 stimulation was studied in subconfluent porcine aortic endothelial (PAE) cells expressing VEGFR-2 (PAE-VEGFR-2) Waltenberger *et al.*, *J. Biol. Chem.*, 269:26988-26995 (1994), which were starved overnight in serum-free medium containing 0.2% BSA. Stimulation was carried out and the lysates prepared as described above. For receptor immunoprecipitation, specific antiserum for VEGFR-2 (Waltenberger *et al.*, *J. Biol. Chem.*, 269:26988-26995 (1994) was used. The immunoprecipitates were analyzed as described for VEGFR-3 in 7% SDS-PAGE followed by Western blotting with anti-phosphotyrosine antibodies, stripping of the filter, and re-probing it with anti-VEGFR-2 antibodies (Santa Cruz).

Mouse VEGF-C appeared to be a potent inducer of VEGFR-3 autophosphorylation, with the  $195 \times 10^3$  M<sub>r</sub> precursor and proteolytically cleaved  $125 \times 10^3$  M<sub>r</sub> tyrosine kinase polypeptides of the receptor (Pajusola *et al.*, *Oncogene*, 9:3545-3555 (1994)), being phosphorylated. VEGFR-2 stimulation was first tried with unconcentrated medium from cells expressing recombinant VEGF-C, but immunoblotting analysis did not reveal any receptor autophosphorylation.

To further determine whether mouse recombinant VEGF-C can also induce VEGFR-2 autophosphorylation as has been previously reported for human VEGF-C (Joukov *et al.*, *EMBO J.*, 15:290-298 (1996)), PAE cells expressing VEGFR-2 were stimulated with tenfold concentrated medium from cultures transfected with mouse VEGF-C expression vector and autophosphorylation was analyzed. For comparison, cells treated with tenfold concentrated medium containing human recombinant VEGF-C (Joukov *et al.*, (1996)), unconcentrated medium from human VEGF-C baculovirus infected insect cells, or pervanadate (a tyrosyl phosphatase inhibitor) were used. As can be seen from Fig. 32B, in response to human baculoviral VEGF-C as well as pervanadate treatment, VEGFR-2 was prominently phosphorylated, whereas human and mouse recombinant VEGF-C gave a weak and barely detectable

enhancement of autophosphorylation, respectively. Media from cell cultures transfected with empty vector or VEGF-C cloned in the antisense orientation did not induce autophosphorylation of VEGFR-2. Therefore, mouse VEGF-C binds to VEGFR-3 and activates this receptor at a much lower concentration than needed for the activation of VEGFR-2. Nevertheless, the invention comprehends methods for using the materials of the invention to take advantage of the interaction of VEGF-C with VEGFR-2, in addition to the interaction between VEGF-C and VEGFR-3.

#### Example 27

##### 10 VEGF-C T103-S213 fragment expressed in *Pichia* yeast stimulates autophosphorylation of Flt4 (VEGFR-3) and KDR (VEGFR-2)

A truncated form of human VEGF-C cDNA was constructed wherein (1) the sequence encoding residues of the putative mature VEGF-C amino terminus H<sub>2</sub>N-E(104)ETIK (SEQ ID NO: 33, residues 104 et seq.) was fused to the yeast PHO1 signal sequence, and (2) a stop codon was introduced after amino acid 213 (H<sub>2</sub>N- ...RCMS; i.e., after codon 213 of SEQ ID NO: 15 32). The resultant truncated cDNA construct was then inserted into the *Pichia pastoris* expression vector pHIL-S1. The engineering of this construct is schematically illustrated in Figure 25. For the cloning, an internal *Bgl*II site in the VEGF-C coding sequence was mutated without change of the encoded 20 polypeptide sequence.

This VEGF-C expression vector was then transfected into *Pichia* cells and positive clones were identified by screening for the expression of VEGF-C protein in the culture medium by Western blotting. One positive 25 clone was grown in a 50 ml culture, and induced with methanol for various periods of time from 0 to 60 hours. About 10 µl of medium was analyzed by gel electrophoresis, followed by Western blotting and detection with anti-VEGF-C antiserum, as described above. As can be seen in Figure 26A, an approximately 24 kD polypeptide (note the band spreading due to 30 glycosylation) accumulates in the culture medium of cells transfected with the recombinant VEGF-C construct, but not in the medium of mock-transfected cells or cells transfected with the vector alone.

The medium containing the recombinant VEGF-C protein was concentrated by Centricon 30 kD cutoff ultrafiltration and used to stimulate

NIH 3T3 expressing Flt4 (VEGFR-3) and porcine aortic endothelial (PAE) cells expressing KDR (VEGFR-2). The stimulated cells were lysed and immunoprecipitated using VEGFR-specific antisera and the immunoprecipitates were analyzed by Western blotting using anti-phosphotyrosine antibodies, chemiluminescence, and fluorography. As a positive control for maximal autophosphorylation of the VEGFRs, vanadate ( $\text{VO}_3$ ) treatment of the cells for 10 min was used. As can be seen from the results shown in Fig. 26B, medium from *Pichia* cultures secreting this recombinant VEGF-C polypeptide induces autophosphorylation of both Flt4 polypeptides of 195 kD and 125 kD as well as the KDR polypeptide of about 200 kD. Vanadate, on the other hand, induces heavy tyrosyl phosphorylation of the receptor bands in addition to other bands probably coprecipitating with the receptors.

These results demonstrate that a VEGF-homologous domain of VEGF-C consisting of amino acid residues 104E - 213S (SEQ ID NO: 33, residues 104-213) can be recombinantly produced in yeast and is capable of stimulating the autophosphorylation of Flt4 (VEGFR-3) and KDR (VEGFR-2). Recombinant VEGF-C fragments such as the fragment described herein, which are capable of stimulating Flt4 or KDR autophosphorylation are intended as aspects of the invention; methods of using these fragments are also within the scope of the invention.

#### Example 28

##### Properties of the differentially processed forms of VEGF-C

The following oligonucleotides were used to generate a set of VEGF-C variants:

5'- TCTCTTCTGTGCTTGAGTTGAG -3' (SEQ ID NO: 42), used to generate VEGF-C R102S (arginine mutated to serine at position 102 (SEQ ID NO: 33));

5'-TCTCTTCTGTCCCTGAGTTGAG -3' (SEQ ID NO: 43), used to generate VEGF-C R102G (arginine mutated to glycine at position 102 (SEQ ID NO: 33));

5'-TGTGCTGCAGCAAATTTTATAGTCTCTTCTGTGGCGGCGGC  
GGCGCGCGCGCGCTCGCGAGGACC -3' (SEQ ID NO: 44), used to generate VEGF-C  $\Delta$ N (deletion of N-terminal propeptide corresponding to amino acids 32-102 (SEQ ID NO: 33));

5'-CTGGCAGGGAAGTCTAATAATGGAATGAA-3' (SEQ ID NO: 45), used to generate VEGF-C R226,227S (arginine codons mutated to serines at positions 226 and 227 (SEQ ID NO: 33));

5'-GGGCTCCGCGTCCGAGAGGTCGAGTCCGGACTCGTGATGGT  
5 GATGGTGATGGGCGGCGGCGGCGGCGGGCGCCTCGCGAGGACC-3'  
(SEQ ID NO: 46), used to generate VEGF-C NHis (this construct encodes a polypeptide with a 6xHis tag fused to the N-terminus of the secreted precursor (amino acid 32 of SEQ ID NO: 33)).

Some of the foregoing VEGF-C variant constructs were further  
10 modified to obtain additional constructs. For example, VEGF-C R102G in pALTER and oligonucleotide 5'-  
GTATTATAATGTCCTCCACCAAATTTTATAG-3' (SEQ ID NO: 47) were  
used to generate VEGF-C 4G, which encodes a polypeptide with four point  
mutations: R102G, A110G, A111G, and A112G (alanines mutated to glycines  
15 at positions 110-112 (SEQ ID NO: 33). These four mutations are adjacent to predicted sites of cleavage of VEGF-C expressed in PC-3 and recombinantly expressed in 293 EBNA cells.

Another construct was created using VEGF-C  $\Delta$ N and  
oligonucleotide 5'-GTTTCGCTGCCTGACACTGTGGTAGTGTGCTGGC  
20 GGCCGCTAGTGATGGTGATGGTGATGAATAATGGAATGAACTTGTCT  
GTAAACATCCAG-3' (SEQ ID NO: 48) to generate VEGF-C  $\Delta$ N $\Delta$ CHis.  
This construct encodes a polypeptide with a deleted N-terminal propeptide (amino acids 32-102); a deleted C-terminal propeptide (amino acids 226-419 of  
SEQ ID NO: 33); and an added 6xHis tag at the C-terminus.

25 All constructs were further digested with *Hind*III and *Not*I, subcloned into *Hind*III/*Not*I digested pREP7 vector, and used to transfect 293 EBNA cells. About 48 hours after transfection, the cells were either metabolically labelled with <sup>35</sup>S as described above, or starved in serum-free medium for 2 days. Media were then collected and used in subsequent  
30 experiments. As can be seen from Figs. 27A-B, wild type (wt) VEGF-C, VEGF-C NHis and VEGF-C  $\Delta$ N $\Delta$ CHis were expressed to similar levels in 293 EBNA cells. At the same time, expression of the VEGF-C 4G polypeptide was considerably lower, possibly due to the changed conformation and decreased stability of the translated product. However, all the above VEGF-C  
35 variants were secreted from the cells (compare Figs. 27A and 27B). The

conditioned media from the transfected and starved cells were concentrated 5-fold and used to assess their ability to stimulate tyrosine phosphorylation of Flt4 (VEGFR-3) expressed in NIH 3T3 cells and KDR (VEGFR-2) expressed in PAE cells.

5 Figs. 28A-B show that wt VEGF-C, as well as all three mutant polypeptides, stimulate tyrosine phosphorylation of VEGFR-3. The most prominent stimulation is by the short mature VEGF-C  $\Delta$ NACHis. This mutant, as well as VEGF-C NHis, also stimulated tyrosine phosphorylation of VEGFR-2. Thus, despite the fact that a major component of secreted  
10 recombinant VEGF-C is a dimer of 32/29 kD, the active part of VEGF-C responsible for its binding to VEGFR-3 and VEGFR-2 is localized between amino acids 102 and 226 (SEQ ID NO: 33) of the VEGF-C precursor. Analysis and comparison of binding properties and biological activities of these VEGF-C proteins and variants, using assays such as those described herein,  
15 will provide data concerning the significance of the observed major 32/29 kD and 21-23 kD VEGF-C processed forms. The data indicate that constructs encoding amino acid residues 103-225 of the VEGF-C precursor (SEQ ID NO: 33) generate a recombinant ligand that is functional for both VEGFR-3 and VEGFR-2.

20 The data from this and preceding examples demonstrate that numerous fragments of the VEGF-C polypeptide retain biological activity. A naturally occurring VEGF-C polypeptide spanning amino acids 103-226 (or 103-227) of SEQ ID NO: 33, produced by a natural processing cleavage defining the C-terminus, has been shown to be active. The foregoing example  
25 demonstrates that a fragment with residues 104-213 of SEQ ID NO: 33 retains biological activity.

In addition, data from Example 21 demonstrates that a VEGF-C polypeptide having its amino terminus at position 112 of SEQ ID NO: 33 retains activity. Additional experiments have shown that a fragment lacking  
30 residues 1-112 of SEQ ID NO: 33 retains biological activity.

In a related experiment, a stop codon was substituted for the lysine at position 214 of SEQ ID NO: 33 (SEQ ID NO: 32, nucleotides 991-993). The resulting recombinant polypeptide still was capable of inducing Flt4 autophosphorylation, indicating that a peptide spanning amino acid residues  
35 113-213 of SEQ ID NO: 33 is biologically active.

Sequence comparisons of members of the VEGF family of polypeptides provides an indication that still smaller fragments of the polypeptide depicted in SEQ ID NO: 33 will retain biological activity. In particular, eight highly conserved cysteine residues of the VEGF family of polypeptides define a region from residues 131 - 211 of SEQ ID NO: 33 (see Figure 32B) of evolutionary significance; therefore, a polypeptide spanning from about residue 131 to about residue 211 is expected to retain VEGF-C biological activity. In fact, a polypeptide which retains the conserved motif RCXXCC (e.g., a polypeptide comprising from about residue 161 to about residue 211 of SEQ ID NO: 33 is postulated to retain VEGF-C biological activity. To maintain native conformation of these fragments, it may be preferred to retain about 1-2 additional amino acids at the carboxy-terminus and 1-2 or more amino acids at the amino terminus.

Beyond the preceding considerations, evidence exists that smaller fragments and/or fragment variants which lack the conserved cysteines nonetheless will retain VEGF-C biological activity. In particular, VEGF-C that has been reduced and alkylated (processes that interfere with the chemistry of cysteine residues) retains biological activity. Consequently, the materials and methods of the invention include all VEGF-C fragments and variants that retain at least one biological activity of VEGF-C, regardless of the presence or absence of members of the conserved set of cysteine residues.

#### Example 29

**Expression of human VEGF-C under the human K14 keratin promoter in transgenic mice induces abundant growth of lymphatic vessels in the skin**

The FLT4 receptor tyrosine kinase is relatively specifically expressed in the endothelia of lymphatic vessels. Kaipainen *et al.*, *Proc. Natl. Acad. Sci. (USA)*, 92: 3566-3570 (1995). Furthermore, the VEGF-C growth factor stimulates the FLT4 receptor, showing at least 10 to 100 fold less activity towards the KDR receptor of blood vessels (Joukov *et al.*, *EMBO J.*, 15: 290-298 (1996); Kukk *et al.*, submitted for publication).

Experiments were conducted in transgenic mice to analyze the specific effects of VEGF-C overexpression in tissues. The human K14 keratin promoter is active in the basal cells of stratified squamous epithelia (Vassar *et al.*, *Proc. Natl. Acad. Sci. (USA)*, 86:1563-1567 (1989)) and was used as the

expression control element in the recombinant VEGF-C transgene. The vector containing the K14 keratin promoter is described in Vassar *et al.*, *Genes Dev.*, 5:714-727 (1991) and Nelson *et al.*, *J. Cell Biol.* 97:244-251 (1983).

The recombinant VEGF-C transgene was constructed using the  
5 human full length VEGF-C cDNA (GenBank Acc. No. X94216). This  
sequence was excised from a pCI-neo vector (Promega) with *XhoI/NorI*, and  
the resulting 2027 base pair fragment containing the open reading frame and  
stop codon (nucleotides 352-1611 of SEQ ID NO: 32) was isolated. The  
isolated fragment was then subjected to an end-filling reaction using the  
10 Klenow fragment of DNA polymerase. The blunted fragment was then ligated  
to a similarly opened *BamHI* restriction site in the K14 vector. The resulting  
construct contained the *EcoRI* site derived from the polylinker of the pCI-neo  
vector. This *EcoRI* site was removed using standard techniques (a Klenow-  
mediated fill-in reaction following partial digestion of the recombinant  
15 intermediate with *EcoRI*) to facilitate the subsequent excision of the DNA  
fragment to be injected into fertilized mouse oocytes. The resulting clone,  
designated K14-VEGF-C, is illustrated in Fig. 20.

The *EcoRI-HindIII* fragment from clone K14 VEGF-C  
containing the K14 promoter, VEGF-C cDNA, and K14 polyadenylation signal  
20 was isolated and injected into fertilized oocytes of the FVB-NIH mouse strain.  
The injected zygotes were transplanted to oviducts of pseudopregnant C57BL/6  
x DBA/2J hybrid mice. The resulting founder mice were analyzed for the  
presence of the transgene by polymerase chain reaction of tail DNA using the  
primers: 5'-CATGTACGAACCGCCAG-3' (SEQ ID NO: 49) and 5'-  
25 AATGACCAGAGAGAGGCGAG-3' (SEQ ID NO: 50). In addition, the tail  
DNAs were subjected to *EcoRV* digestion and subsequent Southern analysis  
using the *EcoRI-HindIII* fragment injected into the mice. Out of 8 pups  
analyzed at 3 weeks of age, 2 were positive, having approximately 40-50  
copies and 4-6 copies of the transgene in their respective genomes.

30 The mouse with the high copy number transgene was small,  
developed more slowly than its litter mates and had difficulty eating (*i.e.*,  
suckling). Further examination showed a swollen, red snout and poor fur.  
Although fed with a special liquid diet, it suffered from edema of the upper  
respiratory and digestive tracts after feeding and had breathing difficulties.  
35 This mouse died eight weeks after birth and was immediately processed for

histology, immunohistochemistry, and *in situ* hybridization.

Histological examination showed that in comparison to the skin of littermates, the dorsal dermis of K14-VEGF-C transgenic mice was atrophic and connective tissue was replaced by large lacunae devoid of red cells, but  
5 lined with a thin endothelial layer (white arrows in Figs. 29A-D). These distended vessel-like structures resembled those seen in human lymphangiomas. The number of skin adnexal organs and hair follicles were reduced. In the snout region, an increased number of vessels was also seen. Therefore, VEGF-C overexpression in the basal epidermis is capable of  
10 promoting the growth of extensive vessel structure in the underlying skin, including large vessel lacunae. The vessel morphology indicates that VEGF-C stimulates the growth of vessels having features of lymphatic vessels.

The foregoing *in vivo* data indicates utilities for both (i) VEGF-C polypeptides and polypeptide variants having VEGF-C biological activity,  
15 and (ii) anti-VEGF-C antibodies and VEGF-C antagonists that inhibit VEGF-C activity (e.g., by binding VEGF-C or interfering with VEGF-C/receptor interactions. For example, the data indicates a therapeutic utility for VEGF-C polypeptides in patients wherein growth of lymphatic tissue may be desirable (e.g., in patients following breast cancer or other surgery where lymphatic  
20 tissue has been removed and where lymphatic drainage has therefore been compromised, resulting in swelling; or in patients suffering from elephantiasis). The data indicates a therapeutic utility for anti-VEGF-C antibody substances and VEGF-C antagonists for conditions wherein growth-inhibition of lymphatic tissue may be desirable (e.g., treatment of  
25 lymphangiomas). Accordingly, methods of administering VEGF-C and VEGF-C variants and antagonists are contemplated as methods and materials of the invention.

### Example 30

#### Expression of VEGF-C and FLT4 in the Developing Mouse

30 Embryos from a 16-day post-coitus pregnant mouse were prepared and fixed in 4% paraformaldehyde (PFA), embedded in paraffin, and sectioned at 6  $\mu$ m. The sections were placed on silanated microscope slides and treated with xylene, rehydrated, fixed for 20 minutes in 4% PFA, treated with proteinase K (7mg/ml; Merck, Darmstadt, Germany) for 5 minutes at

room temperature, again fixed in 4% PFA and treated with acetic anhydride, dehydrated in solutions with increasing ethanol concentrations, dried and used for *in situ* hybridization.

In situ hybridization of sections was performed as described (Västrik *et al.*, *J. Cell Biol.*, 128:1197-1208 (1995)). A mouse VEGF-C antisense RNA probe was generated from linearized pBluescript II SK+ plasmid (Stratagene Inc.), containing a fragment corresponding to nucleotides 499-979 of mouse VEGF-C cDNA, where the noncoding region and the BR3P repeat were removed by Exonuclease III treatment. The fragment had been cloned into the *EcoRI* and *HindIII* sites of pBluescript II SK+. Radiolabeled RNA was synthesized using T7 RNA Polymerase and [<sup>35</sup>S]-UTP (Amersham, Little Chalfont, UK). About two million cpm of the VEGF-C probe was applied per slide. After an overnight hybridization, the slides were washed first in 2x SSC and 20-30 mM DTT for 1 hour at 50°C. Treatment continued with a high stringency wash, 4x SSC and 20 mM DTT and 50% deionized formamide for 30 minutes at 65°C followed by RNase A treatment (20 µg/ml) [Is this correct? µg, not mg?] for 30 minutes at 37°C. The high stringency wash was repeated for 45 minutes. Finally, the slides were dehydrated and dried for 30 minutes at room temperature. The slides were dipped into photography emulsion and exposed for 4 weeks. Slides were developed using Kodak D-16 developer, counterstained with hematoxylin and mounted with Permount (FisherChemical).

For *in situ* hybridizations of Flt4 sequences, a mouse Flt4 cDNA fragment covering bp 1-192 of the published sequence (Finnerty *et al.*, *Oncogene*, 8:2293-2298 (1993)) was used, and the above-described protocol was followed, with the following exceptions. Approximately one million cpm of the Flt4 probe were applied to each slide. The stringent washes following hybridization were performed in 1x SSC and 30 mM DTT for 105 minutes.

The figure shows photomicrographs of the hybridized sections in dark field microscopy (Figs. 36A-C) and light field microscopy (Fig. 36D). Magnifications used for photography were 4x for Figs. 36A-B and 10x for Figs. 36C-D. The transverse sections shown are from the cephalic region and the area shown for VEGF-C and FLT4 are about 14 sections apart, FLT4 being more cranially located in the embryo. In Fig. 36A (Flt4 probe), the developing nasopharyngeal cavity is in the midline in the upper, posterior part;

in the anterior part of Fig. 36A is the snout with emerging fibrillar follicles and, in the midline, the forming nasal cavity. On both sides, the retinal pigment gives a false positive signal in dark field microscopy. The most prominently FLT4-hybridizing structures appear to correspond to the developing lymphatic and venous endothelium. Note that a plexus-like endothelial vascular structure surrounds the developing nasopharyngeal mucous membrane. In Fig. 36B, the most prominent signal is obtained from the posterior part of the developing nasal conchae, which in higher magnification (Figs. 36C-D) show the epithelium surrounding loose connective tissue/forming cartilage. This structure gives a strong *in situ* hybridization signal for VEGF-C. Also in Fig. 36B, more weakly hybridizing areas can be seen around the snout, although this signal is much more homogeneous in appearance. Thus, the expression of VEGF-C is strikingly high in the developing nasal conchae.

The conchae are surrounded with a rich vascular plexus, important in nasal physiology as a source for the mucus produced by the epithelial cells and for warming inhaled air. It is suggested that VEGF-C is important in the formation of the conchal venous plexus at the mucous membranes, and that it may also regulate the permeability of the vessels needed for the secretion of nasal mucus. Possibly, VEGF-C and its derivatives, and antagonists, could be used in the regulation of the turgor of the conchal tissue and mucous membranes and therefore the diameter of the upper respiratory tract, as well as the quantity and quality of mucus produced. These factors are of great clinical significance in inflammatory (including allergic) and infectious diseases of the upper respiratory tract. Accordingly, the invention contemplates the use of the materials of the invention, including VEGF-C, Flt4, and their derivatives, in methods of diagnosing and treating inflammatory and infectious conditions affecting the upper respiratory tract, including nasal structures.

**Deposit of Biological Materials:** Plasmid FLT4-L has been deposited with the American Type Culture Collection (ATCC), 12301 Parklawn Dr., Rockville MD 20952 (USA), pursuant to the provisions of the Budapest Treaty, and has been assigned a deposit date of 24 July 1995 and  
5 ATCC accession number 97231.

While the present invention has been described in terms of specific embodiments, it is understood that variations and modifications will occur to those in the art. Accordingly, only such limitations as appear in the appended claims should be placed on the invention.

  - (B) TYPE: nucleic acid
  - (C) STRANDEDNESS: single
  - (D) TOPOLOGY: linear

(ii) MOLECULE TYPE: cDNA

(xi) SEQUENCE DESCRIPTION: SEQ ID NO:3:

ACATGCATGC CCCGCCGGTC ATCC 24

(2) INFORMATION FOR SEQ ID NO:4:

- (i) SEQUENCE CHARACTERISTICS:
  - (A) LENGTH: 22 base pairs
  - (B) TYPE: nucleic acid
  - (C) STRANDEDNESS: single
  - (D) TOPOLOGY: linear

(ii) MOLECULE TYPE: cDNA

(xi) SEQUENCE DESCRIPTION: SEQ ID NO:4:

CGGAATTCCC CATGACCCCA AC 22

(2) INFORMATION FOR SEQ ID NO:5:

- (i) SEQUENCE CHARACTERISTICS:
  - (A) LENGTH: 33 base pairs
  - (B) TYPE: nucleic acid
  - (C) STRANDEDNESS: single
  - (D) TOPOLOGY: linear

(ii) MOLECULE TYPE: cDNA

(xi) SEQUENCE DESCRIPTION: SEQ ID NO:5:

CCATCGATGG ATCCTACCTG AAGCCGCTTT CTT 33

(2) INFORMATION FOR SEQ ID NO:6:

- (i) SEQUENCE CHARACTERISTICS:
  - (A) LENGTH: 17 base pairs
  - (B) TYPE: nucleic acid
  - (C) STRANDEDNESS: single
  - (D) TOPOLOGY: linear

(ii) MOLECULE TYPE: cDNA

(xi) SEQUENCE DESCRIPTION: SEQ ID NO:6:

ATTTAGGTGA CACTATA 17

(2) INFORMATION FOR SEQ ID NO:7:

- (i) SEQUENCE CHARACTERISTICS:
  - (A) LENGTH: 34 base pairs
  - (B) TYPE: nucleic acid

(C) STRANDEDNESS: single  
(D) TOPOLOGY: linear

(ii) MOLECULE TYPE: cDNA

(xi) SEQUENCE DESCRIPTION: SEQ ID NO:7:

CCATCGATGG ATCCCGATGC TGCTTAGTAG CTGT

34

(2) INFORMATION FOR SEQ ID NO:8:

(i) SEQUENCE CHARACTERISTICS:  
(A) LENGTH: 40 amino acids  
(B) TYPE: amino acid  
(C) STRANDEDNESS: single  
(D) TOPOLOGY: linear

(ii) MOLECULE TYPE: peptide

(xi) SEQUENCE DESCRIPTION: SEQ ID NO:8:

# CLAIMS

What is claimed is:

1. A purified and isolated polypeptide which is capable of binding to Flt4 receptor tyrosine kinase.
2. A purified and isolated polypeptide according to claim 1, said polypeptide having a molecular weight of approximately 23 kD as determined by SDS-PAGE under reducing conditions.
3. A purified and isolated polypeptide according to claim 2, wherein said polypeptide is capable of stimulating tyrosine phosphorylation of Flt4 receptor tyrosine kinase in a host cell expressing said Flt4 receptor tyrosine kinase.
4. A purified and isolated polypeptide according to claim 2, said polypeptide comprising an amino acid sequence set forth in SEQ ID NO: 13.
5. A purified and isolated polypeptide according to claim 1, said polypeptide capable of being purified from conditioned media from a PC-3 prostatic adenocarcinoma cell line, said cell line having ATCC Accession Number CRL 1435.
6. A purified and isolated polypeptide according to claim 1, said polypeptide being encoded by plasmid pFLT4-L, deposited as ATCC Accession Number 97231.
7. A purified and isolated polypeptide according to claim 1 comprising an amino acid sequence set forth in SEQ ID NO: 33 from about residue 161 of SEQ ID NO: 33 to about residue 211 of SEQ ID NO: 33.
8. A purified and isolated polypeptide according to claim 1 comprising an amino acid sequence set forth in SEQ ID NO: 33 from about residue 131 of SEQ ID NO: 33 to about residue 211 of SEQ ID NO: 33.

9. A purified and isolated polypeptide according to claim 1 comprising an amino acid sequence set forth in SEQ ID NO: 33 from residue 113 of SEQ ID NO: 33 to residue 213 of SEQ ID NO: 33.

10. A purified and isolated polypeptide according to claim 1 comprising amino acids 103 to 217 of SEQ ID NO: 33.

11. A purified and isolated polypeptide according to claim 1 comprising amino acids 103 to 225 of SEQ ID NO: 33.

12. A purified and isolated polypeptide according to claim 1 comprising amino acids 32 to 227 of SEQ ID NO: 33.

13. A purified and isolated polypeptide having the amino acid sequence of residues 1 to 419 of SEQ ID NO: 33.

14. A purified polypeptide comprising a fragment of the polypeptide according to claim 13, wherein said fragment is capable of binding to Flt4 receptor tyrosine kinase.

15. A purified polypeptide according to claim 14 wherein said fragment has an apparent molecular weight of approximately 21 - 23 kD as assessed by SDS-PAGE under reducing conditions.

16. A purified polypeptide according to claim 14 wherein said fragment has an apparent molecular weight of about 32 kD as assessed by SDS-PAGE under reducing conditions.

17. A conditioned medium comprising a polypeptide according to claim 1.

18. A polypeptide according to claim 1 further comprising a detectable label.

19. A purified protein comprising a first polypeptide linked to a second polypeptide, wherein at least one of said first polypeptide and said second polypeptide has an amino acid sequence comprising a portion of the amino acid sequence of SEQ ID NO: 33, and wherein said protein is capable of binding to Flt4 receptor tyrosine kinase.

20. A purified protein according to claim 19 wherein said first polypeptide is covalently linked to said second polypeptide.

21. A purified protein according to claim 19 wherein at least one of said first polypeptide and said second polypeptide comprise an amino acid sequence selected from the group consisting of:

- (a) amino acids 161 to 211 of SEQ ID NO: 33;
- (b) amino acids 131 to 211 of SEQ ID NO: 33;
- (c) amino acids 113 to 213 of SEQ ID NO: 33;
- (d) amino acids 113 to 227 of SEQ ID NO: 33
- (e) amino acids 103 to 217 of SEQ ID NO: 33;
- (f) amino acids 103 to 225 of SEQ ID NO: 33;
- (g) amino acids 103 to 227 of SEQ ID NO: 33; and
- (h) amino acids 32 to 227 of SEQ ID NO: 33.

22. A purified protein according to claim 19 wherein each of said first polypeptide and said second polypeptide comprise an amino acid sequence selected from the group consisting of:

- (a) amino acids 161 to 211 of SEQ ID NO: 33;
- (b) amino acids 131 to 211 of SEQ ID NO: 33;
- (c) amino acids 113 to 213 of SEQ ID NO: 33;
- (d) amino acids 113 to 227 of SEQ ID NO: 33
- (e) amino acids 103 to 217 of SEQ ID NO: 33;
- (f) amino acids 103 to 225 of SEQ ID NO: 33;
- (g) amino acids 103 to 227 of SEQ ID NO: 33; and
- (h) amino acids 32 to 227 of SEQ ID NO: 33.
- (i) amino acids 228 to 419 of SEQ ID NO: 33.

23. A purified and isolated nucleic acid comprising a nucleotide

sequence encoding a polypeptide capable of binding to Flt4 receptor tyrosine kinase, said polypeptide having an amino acid sequence selected from the group consisting of:

- (a) amino acids 161 to 211 of SEQ ID NO: 33;
- (b) amino acids 131 to 211 of SEQ ID NO: 33;
- (c) amino acids 113 to 213 of SEQ ID NO: 33;
- (d) amino acids 113 to 227 of SEQ ID NO: 33;
- (e) amino acids 103 to 217 of SEQ ID NO: 33;
- (f) amino acids 103 to 225 of SEQ ID NO: 33;
- (g) amino acids 103 to 227 of SEQ ID NO: 33;
- (h) amino acids 32 to 227 of SEQ ID NO: 33; and
- (i) amino acids 1 to 419 of SEQ ID NO: 33.

24. A nucleic acid according to claim 23 comprising a nucleotide sequence encoding a polypeptide consisting of amino acids 113 to 213 of SEQ ID NO: 33.

25. A nucleic acid according to claim 23 comprising a nucleotide sequence encoding a polypeptide consisting of amino acids 103 to 217 of SEQ ID NO: 33.

26. A nucleic acid according to claim 23 having the nucleotide sequence of nucleotides 352 to 1608 of SEQ ID NO: 32.

27. A nucleic acid comprising a VEGF-C encoding insert of plasmid pFLT4-L, deposited as ATCC Accession Number 97321.

28. A vector comprising a nucleic acid according to claim 23, 24, or 25.

29. A vector comprising the nucleic acid according to claim 27.

30. A host cell transformed or transfected with a nucleic acid according to claim 23, 24, 25, or 27.

31. An antibody which is specifically reactive with an Flt4 receptor tyrosine kinase ligand.

32. An antibody which is specifically reactive with a polypeptide according to claim 11, 12, or 13.

33. An antibody of claim 31 which is a monoclonal antibody.

34. A pharmaceutical composition comprising a polypeptide fragment according to claim 1 in a pharmaceutically-acceptable diluent, adjuvant, excipient or carrier.

35. A method of making a polypeptide capable of specifically binding to Flt4 receptor tyrosine kinase, said method comprising the steps of:

(a) expressing a nucleic acid according to claim 23, 24, 25, or 27 in a host cell; and

(b) purifying a polypeptide capable of specifically binding to Flt4 receptor tyrosine kinase from said host cell or from a growth medium of said host cell.

36. A polypeptide capable of specifically binding to Flt4 receptor tyrosine kinase, said polypeptide produced by the method according to claim 35.

37. A purified and isolated mammalian VEGF-C polypeptide.

38. A purified and isolated polynucleotide encoding the polypeptide of claim 37.

39. A purified and isolated polypeptide having the amino acid sequence of residues 1 to 415 of SEQ ID NO: 41.

40. A purified and isolated polypeptide capable of specifically binding to an Flt4 receptor tyrosine kinase, said polypeptide comprising a fragment of the purified and isolated polypeptide according to

claim 39, said fragment being capable of specifically binding to said Flt4 receptor tyrosine kinase.

41. A purified and isolated nucleic acid encoding the polypeptide according to claim 39.

42. A purified and isolated nucleic acid having at least about 16 nucleotides, said nucleic acid specifically hybridizing to a human gene encoding VEGF-C.

43. A nucleic acid according to claim 42 which hybridizes to a human gene encoding VEGF-C, under hybridization conditions wherein said nucleic acid fails to hybridize to a human gene encoding VEGF or VEGF-B, and wherein said nucleic acid comprises a continuous nucleotide sequence of at least twenty nucleotides from a nucleotide sequence selected from the group consisting of:

SEQ ID NO: 32, and

a nucleotide sequence complementary to SEQ ID NO: 32.

44. A method for detecting endothelial cells in a biological tissue comprising the steps of:

exposing a biological tissue comprising endothelial cells to a polypeptide according to claim 1, under conditions wherein said polypeptide binds to endothelial cells; and

detecting said polypeptide bound to endothelial cells in said biological tissue, thereby detecting said endothelial cells.

45. The method according to claim 44, further comprising the step of washing said biological tissue, said washing step being performed after said exposing step and before said detecting step.

46. A method of modulating the growth of mammalian endothelial cells comprising the steps of:

exposing mammalian endothelial cells to a polypeptide according to claim 1 in an amount effective to modulate the growth of mammalian

endothelial cells.

47. A method according to claim 46 wherein the polypeptide is capable of stimulating tyrosine phosphorylation of Flt4 receptor tyrosine kinase in a host cell expressing said Flt4 receptor tyrosine kinase.

**ABSTRACT**

Provided are polypeptide ligands for the receptor tyrosine kinase, Flt4. Also provided are cDNAs and vectors encoding the ligands, pharmaceutical compositions and diagnostic reagents comprising the ligands, and methods of making and using the ligands.

## DECLARATION FOR PATENT APPLICATION AND POWER OF ATTORNEY

As a below named inventor, I hereby declare that my residence, post office address and citizenship are as stated below next to my name. I believe that I am an original, first and joint inventor of the subject matter which is claimed and for which a patent is sought on the invention entitled "RECEPTOR LIGAND VEGF-C," the specification of which was filed on June 28, 1996 as Application Serial No. 08/671,573. I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims. I acknowledge the duty to disclose to the Patent and Trademark Office all information known to me to be material to patentability as defined in 37 C.F.R. §1.56.

I hereby claim foreign priority benefits under 35 U.S.C. §119 of any foreign application(s) for patent or inventor's certificate or of any PCT international application(s) designating at least one country other than the United States of America listed below and have also identified below any foreign application(s) for patent or inventor's certificate or any PCT international application(s) designating at least one country other than the United States of America filed by me on the same subject matter having a filing date before that of the application(s) of which priority is claimed:

Priority Claimed  
☐ ☒

(Application Serial Number)	(Country)	(Day/Month/Year Filed)
